# A NEW CLASS OF $\alpha$-FAREY MAPS AND AN APPLICATION TO NORMAL NUMBERS 

K. DAJANI, C. KRAAIKAMP, H. NAKADA, AND R. NATSUI

#### Abstract

We define two types of the $\alpha$-Farey maps $F_{\alpha}$ and $F_{\alpha, b}$ for $0<\alpha<\frac{1}{2}$, which were previously defined only for $\frac{1}{2} \leq \alpha \leq 1$ by R. Natsui (2004). Then, for each $0<\alpha<\frac{1}{2}$, we construct the natural extension maps on the plane and show that the natural extension of $F_{\alpha, b}$ is metrically isomorphic to the natural extension of the original Farey map. As an application, we show that the set of normal numbers associted with $\alpha$-continued fractions does not vary by the choice of $\alpha, 0<\alpha<1$. This extends the result by C. Kraaikamp and H. Nakada (2000).

## 1. Introduction

The main purpose of this paper is to extend the notion of the $\alpha$-Farey map to $0<\alpha<\frac{1}{2}$, and discuss its properties with applications. We start with a simple introduction of the theory of the regular continued fraction map.

Let $x$ be a real number, then it is well-known that the simple or regular continued fraction (RCF) expansion of $x$ yields a finite (if $x \in$ $\mathbb{Q}$ ) or infinite (if $x \in \mathbb{R} \backslash \mathbb{Q})$ sequence of rational convergents $\left(p_{n} / q_{n}\right)$ with extremely good approximation properties; see e.g. [10, 14, 16, 18, 33, 34]. The RCF-expansion of $x$ can be obtained using the so-called Gauss map $G:[0,1] \rightarrow[0,1)$, defined as follows:

$$
G(x)= \begin{cases}\frac{1}{x}-\left\lfloor\frac{1}{x}\right\rfloor, & \text { if } x \neq 0 \\ 0, & \text { if } x=0\end{cases}
$$

For $0<x<1$, the digits (or: partial quotients) $a_{n}=a_{n}(x)$ of the RCF-expansion of $x$ are defined for $n \geq 1$ by $a_{n}(x)=\left\lfloor\frac{1}{G^{n-1}(x)}\right\rfloor$, where $\left\lfloor\frac{1}{0}\right\rfloor=\infty$ and $\frac{1}{\infty}=0$. For $x \in \mathbb{R}$, we define $a_{0}=a_{0}(x)=\lfloor x\rfloor$; if $x \notin$ $(0,1)$, we define for $n \geq 1$ the digit $a_{n}(x)$ by setting $a_{n}(x):=a_{n}\left(x-a_{0}\right)$.

[^0]It is well-known that for $x \in(0,1)$ the simple continued fraction expansion of $x$ easily follows from the above definitions of $G$ and $a_{n}(x)$ :

$$
x=\frac{1}{\mid a_{1}(x)}+\frac{1 \mid}{\mid a_{2}(x)}+\cdots+\frac{1 \mid}{\mid a_{n}(x)}+\cdots .
$$

We put

$$
\frac{p_{n}(x)}{q_{n}(x)}=\frac{1 \mid}{\mid a_{1}(x)}+\frac{1}{\mid a_{2}(x)}+\cdots+\frac{1}{\mid a_{n}(x)},
$$

where $p_{n}(x), q_{n}(x) \in \mathbb{N}$ and where we assume that $\left(p_{n}(x), q_{n}(x)\right)=1$. This rational number $p_{n}(x) / q_{n}(x)$ is called the $n$-th principal convergent of $x$. It is also well known that for $n \geq 1$,

$$
\left\{\begin{array}{l}
p_{n}(x)=a_{n}(x) p_{n-1}(x)+p_{n-2}(x) ; \\
q_{n}(x)=a_{n}(x) q_{n-1}(x)+q_{n-2}(x),
\end{array}\right.
$$

with $p_{-1}(x)=1, p_{0}(x)=0, q_{-1}(x)=0, q_{0}(x)=1$. If $a_{n}(x) \geq 2$ for $n \geq 1$, then

$$
\begin{equation*}
\frac{\ell \cdot p_{n-1}(x)+p_{n-2}(x)}{\ell \cdot q_{n-1}(x)+q_{n-2}(x)}, \quad 1 \leq \ell<a_{n}(x) \tag{1}
\end{equation*}
$$

is called the $(n, \ell)$-mediant (or intermediate) convergent of $x$.
Setting

$$
\Theta_{n}(x)=q_{n}^{2}\left|x-\frac{p_{n}}{q_{n}}\right|, \quad \text { for } n \geq 0
$$

one can easily show that for all irrational $x$ and all $n \geq 1$ one has that $0<\Theta_{n}(x)<1$; see e.g. [10, 16]. Several classical results on these approximation coefficients $\Theta_{n}(x)$ have been obtained for all $n \geq 1$ and all irrational $x$; just to mention a few:

$$
\min \left\{\Theta_{n-1}(x), \Theta_{n}(x)\right\}<\frac{1}{2}, \quad \text { (Vahlen, 1913) }
$$

and

$$
\min \left\{\Theta_{n-1}(x), \Theta_{n}(x), \Theta_{n+1}(x)\right\}<\frac{1}{\sqrt{5}}, \quad \text { (Borel, 1903). }
$$

Borel's result is a consequence of

$$
\min \left\{\Theta_{n-1}(x), \Theta_{n}(x), \Theta_{n+1}(x)\right\}<\frac{1}{\sqrt{a_{n+1}^{2}+4}}
$$

which was obtained independently by various authors; see also Chapter 4 in [10. That the sequence $\left(p_{n}(x) / q_{n}(x)\right)$ converges extremely fast to $x$ follows from $0<\Theta_{n}(x)<1$ for all $n$, and the fact that the sequence $\left(q_{n}(x)\right)$ grows exponentially fast. An old result by Legendre further
underlines the Diophantine qualities of the RCF: let $x \in \mathbb{R}$, and let $p \in \mathbb{Z}, q \in \mathbb{N}$, such that $(p, q)=1$, and suppose we moreover have that

$$
\left|x-\frac{p}{q}\right|<\frac{1}{2} \frac{1}{q^{2}},
$$

then $p / q$ is a RCF-convergent of $x$. I.e., there exists an $n$ such that $p=$ $p_{n}(x)$ and $q=q_{n}(x)$. Here the constant $1 / 2$ is best possible. In 1904, Fatou stated (and this was published in 1918 by Grace; see [13]), that if $\left|x-\frac{p}{q}\right|<\frac{1}{q^{2}}$, then $p / q$ is either an RCF-convergent, or an extreme mediant; i.e., an $(n, \ell)$-mediant convergent of $x$ from (1) with $\ell=1$ or $\ell=a_{n}-1$. Further refinements of this result can be found in [3].

The $(n, \ell)$-mediant convergents of $x$ from (1) can be obtained by the so-called Farey-map $F$. The notion of the Farey map was introduced in 1989 by S. Ito in [15] and by M. Feigenbaum, I. Procaccia and T. Tel in [12] independently. In particular, the metric properties of $F$ were discussed by Ito in [15]; see also [4, 6, 7, 11].

To introduce $F$, we write $G$ as the composition of two maps: an inversion $R:(0,1] \rightarrow[1, \infty)$ and a translation $S:[1, \infty) \rightarrow(0,1]$, defined as:

$$
R(x)=\frac{1}{x}, \quad \text { for } x \in(0,1]
$$

and

$$
S(x)=x-k, \quad \text { if } x \in[k, k+1) \text {, for some } k \in \mathbb{N} .
$$

If we furthermore define that $0 \mapsto 0$, we clearly have that $G(x)=$ $(S \circ R)(x)$ for $x \in(0,1]$. Note that the latter map $S$ can be written as the $k$-fold composition of a map $S_{1}:[1, \infty) \rightarrow[0, \infty)$, defined as $S_{1}(x)=x-1$ for $x \geq 1$, so that $S(x)=(\underbrace{S_{1} \circ \cdots \circ S_{1}}_{k})(x)$.

Next, we extend the inversion $R$ to $[1, \infty): R(x)=\frac{1}{x}$, for $x \in[1, \infty)$ so that we map $[1, \infty)$ bijectively on the bounded interval $(0,1]$. With this extended definition of the map $R$, we define the map $F:(0,1] \rightarrow$ $[0,1)$ as a "slow continued fraction map," given by:

$$
F(x)= \begin{cases}\left(R \circ S_{1} \circ R\right)(x) & =\frac{x}{1-x}, \\ \text { if } x \in[0,1 / 2) \\ G(x)=\left(S_{1} \circ R\right)(x)=\frac{1-x}{x}, & \text { if } x \in[1 / 2,1]\end{cases}
$$

see also [11], where the relation between $F$ and the so-called Lehner continued fraction is investigated.

For a given matrix $A=\left(\begin{array}{ll}a_{11} & a_{12} \\ a_{21} & a_{22}\end{array}\right) \in \mathrm{GL}(2, \mathbb{Z})$, we define its associated linear fractional transformation as:

$$
\begin{equation*}
A(x)=\frac{a_{11} x+a_{12}}{a_{21} x+a_{22}}, \quad \text { for } x \in \mathbb{R} . \tag{2}
\end{equation*}
$$

The map $F$ "yields" the mediant convergents together with the principal (i.e., RCF) convergents in the following manner. For each $x \in(0,1)$, $F(x)$ is either $\frac{x}{1-x}$ or $\frac{1-x}{x}$, which is a linear fractional transformation associated with matrices $\left(\begin{array}{cc}1 & 0 \\ -1 & 1\end{array}\right)$ and $\left(\begin{array}{cc}-1 & 1 \\ 1 & 0\end{array}\right)$, respectively. We put
thus yielding a sequence of matrices $\left(A_{n}: n \geq 1\right)$. Viewing this sequence as a sequence of linear fractional transformations, we obtain a sequence of rationals $\left(t_{n}: n \geq 1\right)$ with $t_{n}=\left(A_{1} A_{2} \cdots A_{n}\right)(-\infty)$, for each $n \geq 1$. It is not hard to see that this sequence is

$$
\begin{aligned}
& \frac{1}{1}, \frac{1}{2}, \ldots, \frac{1}{a_{1}-1} \\
& \frac{0}{1}=\frac{p_{0}}{q_{0}}, \frac{1}{a_{1}+1}=\frac{1 \cdot p_{1}+p_{0}}{1 \cdot q_{1}+q_{0}}, \frac{2 \cdot p_{1}+p_{0}}{2 \cdot q_{1}+q_{0}}, \ldots, \frac{\left(a_{2}-1\right) \cdot p_{1}+p_{0}}{\left(a_{2}-1\right) \cdot q_{1}+q_{0}}, \\
& \frac{p_{1}}{q_{1}}, \frac{1 \cdot p_{2}+p_{1}}{1 \cdot q_{2}+q_{1}}, \frac{2 \cdot p_{2}+p_{1}}{2 \cdot q_{2}+q_{1}}, \ldots, \frac{\left(a_{3}-1\right) \cdot p_{2}+p_{1}}{\left(a_{3}-1\right) \cdot q_{2}+q_{1}}, \\
& \vdots \\
& \frac{p_{n-1}}{q_{n-1}}, \frac{1 \cdot p_{n}+p_{n-1}}{1 \cdot q_{n}+q_{n-1}}, \ldots, \frac{\ell \cdot p_{n}+p_{n-1}}{\ell \cdot q_{n}+q_{n-1}}, \ldots, \frac{\left(a_{n+1}-1\right) \cdot p_{n}+p_{n-1}}{\left(a_{n+1}-1\right) \cdot q_{n}+q_{n-1}}, \\
& \frac{p_{n}}{q_{n}}, \frac{1 \cdot p_{n+1}+p_{n}}{1 \cdot q_{n+1}+q_{n}}, \ldots \ldots .,
\end{aligned}
$$

i.e., we have the sequence of the mediant convergents together with the principal convergents of $x$. We will find it again in $\S 2$ as a special case of H. Nakada's $\alpha$-expansions from [27], with $\alpha=1$.

Apart from the regular continued fraction expansion there is a bewildering amount of other continued fraction expansion: continued fraction expansions with even (or odd) partial quotients, the optimal continued fraction expansion, the Rosen fractions, and many more. In
this paper we will look at a family of continued fraction algorithms, introduced by Nakada in 1981 in [27] with the natural extensions as planer maps. These continued fraction expansions are parameterized by a parameter $\alpha \in(0,1]$, the case $\alpha=1$ being the RCF. After their introduction, the natural extension of the Gauss map played an important role in solving a conjecture by Hendrik Lenstra, which was previously proposed by Wolfgang Doeblin (see [5], and also [10, 16] for more details on the proof and various corollaries of this Doeblin-Lenstra conjecture). The notion of the natural extension planer maps lead to various generalization, e.g. the so-called $S$-expansions, introduced by C. Kraaikamp in [19]. The papers mentioned here, and various other papers at the time dealt with the case $\frac{1}{2} \leq \alpha \leq 1$. At that time, there was no discussion on $\alpha$-continued fractions for $0<\alpha<\frac{1}{2}$ except for a 1999 paper by P. Moussa, A. Casa and S. Marmi ([26]), dealing with $\sqrt{2}-1<\alpha<\frac{1}{2}$. Later on, after two papers published in 2008 by L. Luzzi and Marmi ([25]), and Nakada and R. Natsui ([30]), the interest to work on $\alpha$-continued fractions was rekindled, but then for parameters $\alpha \in\left(0, \frac{1}{2}\right)$; see e.g. [24, 17].

In 2004, Natsui introduced and studied the so-called $\alpha$-Farey maps $F_{\alpha}$ in [31, 32] for parameters $\alpha \in\left[\frac{1}{2}, 1\right)$. These maps $F_{\alpha}$ relate to the $\alpha$-expansion maps $G_{\alpha}$ from [27] as the Farey-map $F$ relates to the Gauss-map $G$. In this paper we investigate these $\alpha$-Farey maps $F_{\alpha}$ for $0<\alpha<\frac{1}{2}$.

Recall from 27 that the $\alpha$-continued fraction map $G_{\alpha}$, for $0<\alpha \leq 1$, is defined $\sqrt{1}$ as follows. Let $\alpha \in(0,1]$ fixed, then for $x \in \mathbb{I}_{\alpha}=[\alpha-1, \alpha)$ we define the map $G_{\alpha}$ as:

$$
G_{\alpha}(x)= \begin{cases}-\frac{1}{x}-\left\lfloor-\frac{1}{x}+1-\alpha\right\rfloor, & \text { if } x<0 ;  \tag{3}\\ 0, & \text { if } x=0 ; \\ \frac{1}{x}-\left\lfloor\frac{1}{x}+1-\alpha\right\rfloor, & \text { if } x>0\end{cases}
$$

For $x \in \mathbb{I}_{\alpha}$, we put $a_{\alpha, n}(x)=\left\lfloor\frac{1}{\left|G_{\alpha}^{n-1}(x)\right|}+1-\alpha\right\rfloor$ and $\varepsilon_{\alpha, n}(x)=\operatorname{sgn}(x)$. Then we have for $x \in \mathbb{I}_{\alpha} \backslash\{0\}$ that:

$$
G_{\alpha}(x)=\frac{\varepsilon_{\alpha, n}(x)}{x}-a_{\alpha, n}(x) .
$$

[^1]From this one easily finds that:

$$
x=\frac{\varepsilon_{\alpha, 1}(x) \mid}{\mid a_{\alpha, 1}(x)}+\frac{\varepsilon_{\alpha, 2}(x) \mid}{\mid a_{\alpha, 2}(x)}+\cdots+\frac{\varepsilon_{\alpha, n}(x) \mid}{\mid a_{\alpha, n}(x)}+\cdots,
$$

which we call the $\alpha$-continued fraction expansion of $x$. We define the $n$-th principal convergent as

$$
\frac{p_{\alpha, n}(x)}{q_{\alpha, n}(x)}=\frac{\varepsilon_{\alpha, 1}(x) \mid}{\mid a_{\alpha, 1}(x)}+\frac{\varepsilon_{\alpha, 2}(x) \mid}{\mid a_{\alpha, 2}(x)}+\cdots+\frac{\varepsilon_{\alpha, n}(x) \mid}{\mid a_{\alpha, n}(x)}, \quad \text { for } n \geq 1
$$

where $p_{\alpha, n}(x) \in \mathbb{Z}, q_{\alpha, n}(x) \in \mathbb{N}$ and $\left(p_{\alpha, n}(x), q_{\alpha, n}(x)\right)=1$. Moreover, whenever $a_{\alpha, n}(x) \geq 2$ we also define the mediant convergents as

$$
\frac{\ell \cdot p_{\alpha, n-1}(x)+\varepsilon_{\alpha, n}(x) p_{\alpha, n-2}(x)}{\ell \cdot q_{\alpha, n-1}(x)+\varepsilon_{\alpha, n}(x) q_{\alpha, n-2}(x)}, \quad \text { for } 1 \leq \ell<a_{n}(x)
$$

To get these mediant convergents, we consider the Farey type map $F_{\alpha}$, and as in the case $\alpha=1$ we show how it is related with $G_{\alpha}$; note that $G_{1}=G$ and $F_{1}=F$. As in the case $\alpha=1$, we consider inversions and a translation. The inversions are now defined by

$$
R_{-}(x)=-\frac{1}{x}, \text { for } x \in[\alpha-1,0), \quad \text { and } \quad R(x)=\frac{1}{x}, \text { for } x>0
$$

while the translation is now defined by

$$
S_{1}(x)=x-1, \quad \text { for } x>\alpha
$$

Of course, we again define that $0 \mapsto 0$. From this process, we have the map $F_{\alpha}$ defined on $\left[\alpha-1, \frac{1}{\alpha}\right]$ by

$$
F_{\alpha}(x)=\left\{\begin{array}{lll}
\left(R \circ S_{1} \circ R_{-}\right)(x)=-\frac{x}{1+x}, & \text { if } x \in[\alpha-1,0)  \tag{4}\\
\left(R \circ S_{1} \circ R\right)(x) & =\frac{x}{1-x}, & \text { if } x \in\left[0, \frac{1}{1+\alpha}\right] ; \\
\left(S_{1} \circ R\right)(x) & =\frac{1-x}{x}, & \text { if } x \in\left(\frac{1}{1+\alpha}, \frac{1}{\alpha}\right]
\end{array}\right.
$$

see Figure 1. We will see in $\S 2$ that the mediant convergents are induced from $F_{\alpha}$. However, we should note that if $\varepsilon_{\alpha, n+1}(x)=-1$,

$$
\frac{1 \cdot p_{\alpha, n}(x)-p_{\alpha, n-1}(x)}{1 \cdot q_{\alpha, n}(x)-q_{\alpha, n-1}(x)}=\frac{\left(a_{\alpha, n}(x)-1\right) \cdot p_{\alpha, n-1}(x)+\varepsilon_{\alpha, n}(x) p_{\alpha, n-2}(x)}{\left(a_{\alpha, n}(x)-1\right) \cdot q_{\alpha, n-1}(x)+\varepsilon_{\alpha, n}(x) q_{\alpha, n-2}(x)}
$$

which means that we get the same rational number more than once as a mediant convergent. To avoid such repetitions, Natsui in 2004 introduced in [31] another type of a Farey like map $F_{\alpha, \text { b }}$ for $\frac{1}{2} \leq \alpha<1$, which is an induced transformation of $F_{\alpha}$, and was defined on $[\alpha-1,1]$

Figure 1. The map $F_{\alpha}$ for $\alpha=\frac{1}{4}$
by

$$
F_{\alpha, b}(x)= \begin{cases}-\frac{x}{1+x}, & \text { if } \alpha-1 \leq x<0  \tag{5}\\ \frac{x}{1-x}, & \text { if } 0 \leq x<\frac{1}{2} \\ \frac{1-2 x}{x}, & \text { if } \frac{1}{2} \leq x \leq \frac{1}{1+\alpha} \\ \frac{1-x}{x}, & \text { if } \frac{1}{1+\alpha}<x \leq 1\end{cases}
$$

The definition of $F_{\alpha, b}$ as given in (5) does not work for the case $0<\alpha<$ $\frac{1}{2}$, since the image of $[\alpha-1,0)$ under $F_{\alpha, b}$ is not contained in $[\alpha-1,1]$. Indeed, $F_{\alpha, b}(\alpha-1)=\frac{1-\alpha}{\alpha}>1$ for $\alpha<1 / 2$. For this reason, we modify the above definition of $F_{\alpha, b}$ slightly; see (8) in § 2. Both are induced transformations, but with a slightly different definition. In the sequel, we first show that $F_{\alpha}$ certainly induces the mediant convergents and is well-defined for $0<\alpha<1 / 2$. Then we introduce a simple variant of $F_{\alpha, b}$. We will show that dynamically these maps are isomorphic to the Farey map $F$ in the following sense. In §3, we construct a planer map $\hat{F}_{\alpha}$ which is the natural extension of $F_{\alpha}$ and then construct in $\S 4$ the natural extension of $F_{\alpha, b}$ (denoted by $\hat{F}_{\alpha, b}$ ) as an induced map of $\hat{F}_{\alpha}$. Then we show that for $0<\alpha<1$, all $\hat{F}_{\alpha, b}$ are metrically isomorphic to $\hat{F}_{1}$. One of the points which we have to be careful is that the first coordinates of planer maps of the "mediant convergent maps $\hat{F}_{\alpha, \text {, }} 0<\alpha<1$ " are not the "mediant convergent maps $F_{\alpha, \text {.", though }}$
the first coordinate of the natural extension maps $\hat{G}_{\alpha}$ are exactly the $\alpha$-continued fraction maps $G_{\alpha}$.

In $\S 5$, we apply the idea of the planer maps to show some results on $\alpha$-continued fractions, which are already known for $\frac{1}{2} \leq \alpha \leq 1$ but not for $0<\alpha<\frac{1}{2}$. We recall some results on normal numbers and on mixing properties of $G_{\alpha}$; see [23] and [29], respectively. The first application of the $\alpha$-Farey map is a relation among normal numbers with respect to $\alpha$-continued fractions for different values of $\alpha$. In [23], it was shown that the set of normal numbers with respect to $G_{\alpha}$ is the same for any $\frac{1}{2} \leq \alpha \leq 1$. It is natural to ask whether we can extend the result to $0<\alpha \leq 1$. However, the proof used in [23] does not work. The main point is that the sequence of the principal convergents $\left(\frac{p_{\alpha, n}}{q_{\alpha, n}}: n \geq 1\right)$ is a subsequence of $\left(\frac{p_{n}}{q_{n}}: n \geq 1\right)$ for $\frac{1}{2} \leq \alpha \leq 1$. This also holds for $\sqrt{2}-1 \leq \alpha<\frac{1}{2}$ but not anymore for $0<\alpha<\sqrt{2}-1$. Thus it is easy to follow the proof used in [23] for $\sqrt{2}-1 \leq \alpha<\frac{1}{2}$ but not possible for $\alpha$ below $\sqrt{2}-1$. At this point, we need the $\alpha-$ mediant convergents to discuss normality. The second application is the following. In [29], we show that the $\phi$-mixing property fails for a.e. $\alpha \in\left[\frac{1}{2}, 1\right]$ using the above normal number result. Indeed, the result implies that for a.e. $\alpha \in\left[\frac{1}{2}, 1\right],\left\{G_{\alpha}^{n}(\alpha-1): n \geq 1\right\}$ is dense in $\mathbb{I}_{\alpha}$. Then for any $\varepsilon>0$, we can find $n \geq 1$ such that the size of either the interval $\left[\alpha-1, G_{\alpha}^{n}(\alpha-1)\right]$ or $\left[G_{\alpha}^{n}(\alpha-1), \alpha\right)$ is less than $\varepsilon$. The property called "matching" plays an important role there. It was proved in [27], however it seems that nobody, not even the author of [27], noticed the importance of this property until [30] appeared (after [29]!). It is also easy to see the matching property for $\sqrt{2}-1 \leq \alpha<\frac{1}{2}$ holds, but not easy for $\alpha$ below $\sqrt{2}-1$. After [30] was published, in [8] the complete characterisation of the set of $\alpha$ 's which have the matching property was given together with the proof of a conjecture from [30]. Actually, the matching property holds for almost all $\alpha \in(0,1)$. Together with the result from $\S 5.1$, we show in $\S 5.2$ that $G_{\alpha}$ is not $\phi$-mixing for almost every $\alpha \in(0,1)$. In $\S 5$ the construction of the natural extension $\hat{F}_{\alpha, b}$ of $F_{\alpha, b}$ as a planer map plays an important role.

In this paper, we change the notation in [31] and [32] to adjust for the names of Gauss and Farey:

| [31, 32] |  | this note |
| :---: | :---: | :---: |
| $T_{\alpha}$ | $\rightarrow$ | $G_{\alpha}$ |
| $G_{\alpha}$ | $\rightarrow$ | $F_{\alpha}$ |
| $F_{\alpha}$ | $\rightarrow$ | $F_{\alpha, b}$ |

## 2. Basic properties of the $\alpha$-Farey map $F_{\alpha}, 0<\alpha<1$

First of all, note that there is a strong relation between the maps $G_{\alpha}$ from (3) and $F_{\alpha}$ from (4). For any $\alpha \in(0,1)$, we get $G_{\alpha}$ as a induced transformation of $F_{\alpha}$. This induced transformation is defined as follows.

For each $\alpha \in(0,1)$ and $x \in \mathbb{I}_{\alpha}=[\alpha-1, \alpha)$, we put $j(x)=j_{\alpha}(x)=k$ if $x \neq 0, F_{\alpha}^{\ell}(x) \notin\left(\frac{1}{1+\alpha}, \frac{1}{\alpha}\right], 0 \leq \ell<k$ and $F_{\alpha}^{k}(x) \in\left(\frac{1}{1+\alpha}, \frac{1}{\alpha}\right]$ (note that from definition (4) of $F_{\alpha}$ we then have that $F_{\alpha}^{k+1}(x) \in \mathbb{I}_{\alpha}$, which is the domain of $G_{\alpha}$; see (3)), and $j(0)=0$ if $x=0$ (noting $F_{\alpha}^{\ell}(0)=0$ for any positive integer $\ell$ ). In case $\frac{\sqrt{5}-1}{2}<\alpha<1$ we further define $j(x)=0$ whenever $x \in\left[\frac{1}{\alpha+1}, \alpha\right)$; see also Remark $\mathbb{1}(i)$. As usual, we set that $F_{\alpha}^{0}(x)=x$. Now the induced transformation $F_{\alpha, J}$ is defined as:

$$
F_{\alpha, J}(x)=F_{\alpha}^{j(x)+1}(x), \quad \text { for } x \in \mathbb{I}_{\alpha} .
$$

The next proposition generalizes the result in [31], where $\alpha$ was restricted to the interval $\left[\frac{1}{2}, 1\right]$.

Proposition 1. For any $0<\alpha \leq 1$, we have $G_{\alpha}(x)=F_{\alpha, J}(x)$ for any $x \in \mathbb{I}_{\alpha}$.

Proof. Since $F_{\alpha}(0)=0, F_{\alpha, J}(0)=0=G_{\alpha}(0)$ is trivial. Next we consider the case $x \in[\alpha-1,0)$. If $-\frac{1}{x} \in[(n-1)+\alpha, n+\alpha)$, then $F_{\alpha}(x)=\left(R \circ S_{1} \circ R-\right)(x) \in\left(\frac{1}{(n-1)+\alpha}, \frac{1}{(n-2)+\alpha}\right]$. Thus we get $F_{\alpha}^{n-1}(x) \in\left(\frac{1}{1+\alpha}, \frac{1}{\alpha}\right]$ inductively, and $j(x)=n-1$ in this case. We also see that $F_{\alpha}^{n-1}(x)=-\frac{x}{(n-1) x+1}$ and then $F_{\alpha, J}(x)=F_{\alpha}^{j(x)+1}(x)=$ $F_{\alpha}\left(-\frac{x}{(n-1) x+1}\right)=\left(-\frac{1}{x}-(n-1)\right)-1=-\frac{1}{x}-n=G_{\alpha}(x)$. For $x \in(0, \alpha)$, the same proof holds since $F_{\alpha}(x)=\left(R \circ S_{1} \circ R\right)(x) \in$ $\left(\frac{1}{(n-1)+\alpha}, \frac{1}{(n-2)+\alpha}\right]$ when $\frac{1}{x} \in[(n-1)+\alpha, n+\alpha)$. The rest of the proof is straightforward.

Remark 1. We gather some results on $j(x)$ for various values of $\alpha$.
(i) $\frac{\sqrt{5}-1}{2}<\alpha<1$.

In this case $\frac{1}{1+\alpha}<\alpha$ holds. It is for this reason we defined $j(x)=0$ for $x \in\left[\frac{1}{\alpha+1}, \alpha\right)$. On the other hand, $j(x) \geq 2$ for $\alpha-1 \leq x<0$.
(ii) $0<\alpha \leq \frac{\sqrt{5}-1}{2}$.

In this case we have $\frac{1}{1+\alpha} \geq \alpha$ and $1+\alpha<\frac{1}{1-\alpha}$, which show that $j(x)=0$ only for $x=0$, and $j(x)=1$ for $x \in\left[\alpha-1,-\frac{1}{1+\alpha}\right) \cup$ $\left[\frac{1}{2+\alpha}, \alpha\right]$.
(iii) $0<\alpha<\sqrt{2}-1$.

We see that $j(x) \geq 2$ for $x \in(0, \alpha)$.
Setting $A^{-}=\left(\begin{array}{cc}-1 & 0 \\ 1 & 1\end{array}\right), A^{+}=\left(\begin{array}{cc}1 & 0 \\ -1 & 1\end{array}\right)$ and $A^{R}=\left(\begin{array}{cc}-1 & 1 \\ 1 & 0\end{array}\right)$, in view of (2) and (4) we can write $F_{\alpha}$ as:

$$
F_{\alpha}(x)= \begin{cases}A^{-} x, & \text { if } x \in[\alpha-1,0) ; \\ A^{+} x, & \text { if } x \in\left[0, \frac{1}{1+\alpha}\right] ; \\ A^{R} x, & \text { if } x \in\left(\frac{1}{1+\alpha}, \frac{1}{\alpha}\right]\end{cases}
$$

Define

$$
A_{n}(x)=A\left(F_{\alpha}^{n-1}(x)\right)= \begin{cases}\left(\begin{array}{cc}
-1 & 0 \\
1 & 1
\end{array}\right)=\left(A^{-}\right)^{-1}, & \text { if } F_{\alpha}^{n-1}(x) \in[\alpha-1,0) ; \\
\left(\begin{array}{cc}
1 & 0 \\
0 & 1
\end{array}\right), & \text { if } F_{\alpha}^{n-1}(x)=0 ; \\
\left(\begin{array}{cc}
1 & 0 \\
1 & 1
\end{array}\right)=\left(A^{+}\right)^{-1}, & \text { if } F_{\alpha}^{n-1}(x) \in\left(0, \frac{1}{1+\alpha}\right] ; \\
\left(\begin{array}{ll}
0 & 1 \\
1 & 1
\end{array}\right)=\left(A^{R}\right)^{-1}, & \text { if } F_{\alpha}^{n-1}(x) \in\left(\frac{1}{1+\alpha}, \frac{1}{\alpha}\right]\end{cases}
$$

for $x \in \mathbb{I}_{\alpha}$ and $n \geq 1$. We identify $x$ with $\left(A_{1}(x), A_{2}(x), \ldots, A_{n}(x), \ldots\right)$. We will show that

$$
\lim _{n \rightarrow \infty}\left(A_{1}(x) A_{2}(x) \cdots A_{n}(x)\right)(-\infty)=x
$$

$\operatorname{Put}\left(\begin{array}{ll}s_{n} & u_{n} \\ t_{n} & v_{n}\end{array}\right)=A_{1}(x) A_{2}(x) \cdots A_{n}(x)$ with $\left(\begin{array}{cc}s_{0} & u_{0} \\ t_{0} & v_{0}\end{array}\right)=\left(\begin{array}{cc}1 & 0 \\ 0 & 1\end{array}\right)$. Suppose that

$$
x=\frac{\varepsilon_{\alpha, 1}(x) \mid}{\mid a_{\alpha, 1}(x)}+\frac{\varepsilon_{\alpha, 2}(x) \mid}{\mid a_{\alpha, 2}(x)}+\cdots+\frac{\varepsilon_{\alpha, n}(x) \mid}{\mid a_{\alpha, n}(x)}+\cdots
$$

is the $\alpha$-continued fraction expansion of $x \in \mathbb{I}_{\alpha}$. Recall that $\varepsilon_{\alpha, n}(x)=$ $\operatorname{sgn}\left(G_{\alpha}^{n-1}(x)\right)$ and $a_{\alpha, n}(x)=\left\lfloor\frac{1}{\left|G_{\alpha}^{n-1}(x)\right|}+1-\alpha\right\rfloor$ for $G_{\alpha}^{n-1}(x) \neq 0$. Then, from Proposition 1, it is easy to see that $\left(A_{1}(x), A_{2}(x), \ldots, A_{n}(x), \ldots\right)$ is of the form

$$
\begin{equation*}
(A^{ \pm}, \underbrace{A^{+}, \ldots, A^{+}}_{a_{\alpha, 1}(x)-2}, A^{R}, A^{ \pm}, \underbrace{A^{+}, \ldots, A^{+}}_{a_{\alpha, 2}(x)-2}, A^{R}, \ldots) \tag{6}
\end{equation*}
$$

unless $A_{m}=\left(\begin{array}{ll}1 & 0 \\ 0 & 1\end{array}\right)$ appears in (6) for some $m \geq 1$ (which happens when $x \in \mathbb{Q})$. Here $A^{ \pm}=A^{-}$or $A^{+}$according to $\varepsilon_{\alpha, n}(x)=-1$ or +1 ,
respectively. If $a_{\alpha, n}(x)=1$, then we read $a_{\alpha, n}-2=0$ and delete $A^{ \pm}$ before $A^{+}$. More precisely,

$$
\begin{aligned}
& A_{\sum_{j=1}^{n} a_{\alpha, j}(x)}(x)=A^{R} ; \\
& A_{\sum_{j=1}^{n} a_{\alpha, j}(x)+1}(x)=\left\{\begin{array}{cc}
A^{-}, & \text {if } \varepsilon_{\alpha, n}(x)=-1 ; \\
A^{+}, & \text {if } \varepsilon_{\alpha, n}(x)=+1 \\
A_{\sum_{j=1}^{n} a_{\alpha, j}(x)+\ell}(x)=A^{+} \quad \text { if } 2 \leq \ell<a_{\alpha, n+1},
\end{array} \text { and } a_{\alpha, n+1}(x) \geq 2 ;\right.
\end{aligned}
$$

with $\sum_{j=1}^{0} a_{\alpha, j}(x)=0$. As usual, we have for the $G_{\alpha}$-convergents of $x$ that:

$$
\left(\begin{array}{cc}
0 & \varepsilon_{\alpha, 1}(x) \\
1 & a_{\alpha, 1}(x)
\end{array}\right)\left(\begin{array}{cc}
0 & \varepsilon_{\alpha, 2}(x) \\
1 & a_{\alpha, 2}(x)
\end{array}\right) \cdots\left(\begin{array}{cc}
0 & \varepsilon_{\alpha, n}(x) \\
1 & a_{\alpha, n}(x)
\end{array}\right)=\left(\begin{array}{cc}
p_{\alpha, n-1}(x) & p_{\alpha, n}(x) \\
q_{\alpha, n-1}(x) & q_{\alpha, n}(x)
\end{array}\right) .
$$

We have the following result.
Lemma 1. For $k, n \in \mathbb{N}$, let $\Pi_{k}(x):=A_{1}(x) A_{2}(x) \cdots A_{k}(x)$, and $S_{n}(x)=\sum_{j=1}^{n} a_{\alpha, j}(x)$. Then, if $k=S_{n}(x)$,

$$
\Pi_{k}(x)=\left(\begin{array}{cc}
p_{\alpha, n-1}(x) & p_{\alpha, n}(x) \\
q_{\alpha, n-1}(x) & q_{\alpha, n}(x)
\end{array}\right) .
$$

Furthermore, if $\ell \geq 1$ and $k=S_{n}(x)+\ell<S_{n+1}(x)$, we have

$$
\Pi_{k}(x)=\left(\begin{array}{cc}
\ell p_{\alpha, n}(x)+\varepsilon_{\alpha, n+1}(x) p_{\alpha, n-1}(x) & p_{\alpha, n-1}(x) \\
\ell q_{\alpha, n}(x)+\varepsilon_{\alpha, n+1}(x) q_{\alpha, n-1}(x) & q_{\alpha, n-1}(x)
\end{array}\right) .
$$

Proof. The assertion of this lemma follows from an easy induction and is essentially due to the fact that $G_{\alpha}$ is an induced transformation of $F_{\alpha}$.

With this result in mind, and analogously to the regular case (which is $\alpha=1$ ), we call

$$
\left(A_{1}(x) A_{2}(x) \cdots A_{k}(x)\right)(-\infty)=\frac{\ell p_{\alpha, n}(x)+\varepsilon_{\alpha, n+1} p_{\alpha, n-1}(x)}{\ell q_{\alpha, n}(x)+\varepsilon_{\alpha, n+1} q_{\alpha, n-1}(x)}
$$

the $((n+1, \ell)$-th) $\alpha$-mediant convergent of $x$ for $\ell>0$; see also (11) for the case $\alpha=1$.

Remark 2. For $0<\alpha \leq \frac{\sqrt{5}-1}{2}, a_{\alpha, n}(x) \geq 2$ for any $x \in \mathbb{I}_{\alpha}$ and $n \geq 1$.

From Lemma 1, the convergence of the mediant convergents follows:
Proposition 2. We have

$$
\lim _{k \rightarrow \infty}\left(\Pi_{k}(x)\right)(-\infty)=x
$$

Proof. If $x$ is rational, then the assertion follows easily. So we estimate $\left|x-\left(\Pi_{k}(x)\right)(-\infty)\right|$ for an irrational $x$. We note that $\left(q_{\alpha, n}(x): n \geq 1\right)$ is strictly increasing for any $x \in \mathbb{I}_{\alpha} \backslash \mathbb{Q}$, which follows from the fact that $a_{\alpha, n}(x) \geq 2$ if $\varepsilon_{\alpha, n}(x)=-1$ (for any $\alpha, 0<\alpha \leq 1$ ). This implies $\lim _{n \rightarrow \infty} q_{\alpha, n}(x)=\infty$ if $x$ is irrational. As for the RCF, see e.g. [10] or (1.1.14) in [16], $x$ can be written as:

$$
\begin{equation*}
\frac{\left(\ell p_{\alpha, n}(x) \pm p_{\alpha, n-1}(x)\right) F_{\alpha}^{k}(x)+p_{\alpha, n-1}(x)}{\left(\ell q_{\alpha, n}(x) \pm q_{\alpha, n-1}(x)\right) F_{\alpha}^{k}(x)+q_{\alpha, n-1}(x)} \text { or } \frac{p_{\alpha, n-1}(x) G_{\alpha}^{n}(x)+p_{\alpha, n}(x)}{q_{\alpha, n-1}(x) G_{\alpha}^{n}(x)+q_{\alpha, n}(x)} . \tag{7}
\end{equation*}
$$

The estimate of the latter is easy since $\left(\Pi_{k}(x)\right)(-\infty)=\frac{p_{\alpha, n-1}(x)}{q_{\alpha, n-1}(x)},\left|G_{\alpha}^{n}(x)\right|$ $<\max (\alpha, 1-\alpha)<1$, and $\left|p_{\alpha, n-1}(x) q_{\alpha, n}(x)-p_{\alpha, n}(x) q_{\alpha, n-1}(x)\right|=1$. Anyway, it is the convergence estimate of the $\alpha$-continued fraction expansion of $x$. In the former case, we see that $\left|x-\left(\Pi_{k}(x)\right)(-\infty)\right|$ is equal to:

$$
\left|\frac{\left(\ell p_{\alpha, n}(x) \pm p_{\alpha, n-1}(x)\right) F_{\alpha}^{k}(x)+p_{\alpha, n-1}(x)}{\left(\ell q_{\alpha, n}(x) \pm q_{\alpha, n-1}(x)\right) F_{\alpha}^{k}(x)+q_{\alpha, n-1}(x)}-\frac{\ell p_{\alpha, n}(x) \pm p_{\alpha, n-1}(x)}{\ell q_{\alpha, n}(x) \pm q_{\alpha, n-1}(x)}\right|
$$

with $k=\sum_{j=1}^{n} a_{\alpha, j}(x)+\ell$. This can be estimated as

$$
\begin{aligned}
& \left|\frac{\ell}{\left(\left(\ell q_{\alpha, n}(x) \pm q_{\alpha, n-1}(x)\right) F_{\alpha}^{k}(x)+q_{\alpha, n-1}(x)\right)\left(\ell q_{\alpha, n}(x) \pm q_{\alpha, n-1}(x)\right)}\right| \\
= & \left|\frac{1}{\left(q_{\alpha, n}(x) \pm \frac{q_{\alpha, n-1}(x)}{\ell}\right)\left(\left(\ell q_{\alpha, n}(x) \pm q_{\alpha, n-1}(x)\right) F_{\alpha}^{k}(x)+q_{\alpha, n-1}(x)\right)}\right| \\
< & \frac{1}{q_{\alpha, n-1}(x)} \rightarrow \quad \rightarrow \quad 0
\end{aligned}
$$

Here we used the fact $F_{\alpha}^{k}(x) \geq 0$ for $k$ not of the form $\sum_{j=1}^{n} a_{\alpha, j}(x)$.
As mentioned in the introduction, the ( $\left.n+1, a_{\alpha, n+1}(x)-1\right)$-th convergent is the same as the $(n+2,1)$-th convergent if $\varepsilon_{\alpha, n+2}(x)=-1$, i.e.,

$$
\frac{\left(a_{\alpha, n+1}(x)-1\right) p_{\alpha, n}(x)+\varepsilon_{\alpha, n+1}(x) p_{\alpha, n-1}(x)}{\left(a_{\alpha, n+1}(x)-1\right) q_{\alpha, n}(x)+\varepsilon_{\alpha, n+1}(x) q_{\alpha, n-1}(x)}=\frac{p_{\alpha, n+1}(x)-p_{\alpha, n}(x)}{q_{\alpha, n+1}(x)-q_{\alpha, n}(x)}
$$

In this sense, the map $F_{\alpha}$ makes a duplication if $\varepsilon_{\alpha, n}(x)=-1$. This duplication is $k$-fold if $\left(\varepsilon_{\alpha, n+\ell}(x), a_{\alpha, n+\ell}(x)\right)=(-1,2)$ for $1 \leq \ell \leq k$,
i.e.,

$$
\begin{aligned}
\frac{p_{\alpha, n}(x)-p_{\alpha, n-1}(x)}{q_{\alpha, n}(x)-q_{\alpha, n-1}(x)} & =\frac{p_{\alpha, n+1}(x)-p_{\alpha, n}(x)}{q_{\alpha, n+1}(x)-q_{\alpha, n}(x)}=\cdots \\
& =\frac{p_{\alpha, n+k}(x)-p_{\alpha, n+k-1}(x)}{q_{\alpha, n+k}(x)-q_{\alpha, n+k-1}(x)}
\end{aligned}
$$

We avoid this duplication using a suitable induced transformation. First, let us recall the definition of $F_{\alpha, b}$ for $\frac{1}{2} \leq \alpha<1$; see (15). One can see that this map skips the ( $n, a_{n+1}(x)-1$ )-th mediant convergent of $x \in \mathbb{I}_{\alpha}$ with $\varepsilon_{n+1}(x)=-1$. An important observation in [31] is that for $\frac{1}{2} \leq \alpha<1$ we have that $-\frac{x}{1+x}<1$ for any $\alpha-1 \leq x<0$. This does not apply anymore when $0<\alpha<\frac{1}{2}$, as the definition of $F_{\alpha, b}$ should be on the interval $[\alpha-1,1]$. To achieve this we "speed up" $F_{\alpha}$ and modify the definition of $F_{\alpha, b}$ as follows:

$$
F_{\alpha, b}(x)=F_{\alpha}^{K(x)}(x),
$$

with $K(x)=\min \left\{k \geq 1: F_{\alpha}^{k}(x) \in[\alpha-1,1]\right.$.
For $\alpha-1 \leq x<-\frac{1}{2}, F_{\alpha}(x)=-\frac{x}{1+x}>1$ (see also (4)), so $F_{\alpha}^{2}(x) \in$ $\mathbb{I}_{\alpha}$. Thus $K(x)=2$ and we have that $F_{\alpha}^{K(x)}(x)=\frac{1+2 x}{x}$ in this case. For $x \in\left[-\frac{1}{2}, \frac{1}{2}\right)$, one can easily see that $F_{\alpha}(x) \in[0,1]$ and the same holds also for $x \in\left[\frac{1}{1+\alpha}, 1\right]$. For $x \in\left[\frac{1}{2}, \frac{1}{1+\alpha}\right)$, we find that $K(x)=2$ and $F_{\alpha, b}(x)=\frac{1-2 x}{x}$. Consequently, our new definition of $F_{\alpha, b}$ is the following:

$$
F_{\alpha, b}(x)= \begin{cases}F_{\alpha}^{2}(x)=-\frac{1+2 x}{x}, & \text { if } \alpha-1 \leq x<-\frac{1}{2}  \tag{8}\\ F_{\alpha}(x)=-\frac{x}{1+x}, & \text { if }-\frac{1}{2} \leq x<0 \\ F_{\alpha}(x)=\frac{x}{1-x}, & \text { if } 0 \leq x<\frac{1}{2} \\ F_{\alpha}^{2}(x)=\frac{1-2 x}{x}, & \text { if } \frac{1}{2} \leq x<\frac{1}{1+\alpha} \\ F_{\alpha}(x)=\frac{1-x}{x}, & \text { if } \frac{1}{1+\alpha} \leq x \leq 1\end{cases}
$$

Clearly from (8) we have that for every $x \in[\alpha-1,1]$ the sequence $\left(F_{\alpha, b}^{k}(x)\right)_{k \geq 0}$, which is the orbit of $x$ under $F_{\alpha, b}$, is a subsequence of the sequence $\left(F_{\alpha}^{n}(x)\right)_{n \geq 0}$ (the orbit of $x$ under $F_{\alpha}$ ). But then for every $x \in[\alpha-1,1]$ fixed there exists a (unique) monotonically increasing function $\hat{k}: \mathbb{N} \cup\{0\} \rightarrow \mathbb{N} \cup\{0\}$, such that $F_{\alpha, b}^{k}(x)=F_{\alpha}^{\hat{k}(k)}(x)$. Setting $\hat{k}=\hat{k}(k)$, for $k=0,1, \ldots$, we put

$$
\Pi_{b, k}(x)=\Pi_{\hat{k}}(x) .
$$

From this definition, it is easy to derive the following.
Proposition 3. For any $k \geq 1$, whenever $\varepsilon_{\alpha, n+1}(x)=-1$, the ( $n+$ $\left.1, a_{n+1}-1\right)$-th mediant convergent does not appear for any $n \geq 1$ in
$\left(\Pi_{b, k}(x)(-\infty): k \geq 1\right)$ and all other mediant convergents and all principal convergents of $x$ appear in it.

Another possibility is by skipping $p_{n+1}(x)-p_{n}(x)$ and $q_{n+1}(x)-$ $q_{n}(x)$ instead of $\left.\left(a_{n+1}(x)-1\right)\right) p_{n}(x)+\varepsilon_{n+1}(x) p_{n-1}(x)$ and $\left(a_{n+1}(x)-\right.$ 1)) $q_{n}(x)+\varepsilon_{n+1}(x) q_{n-1}(x)$ if $\varepsilon_{n+1}(x)=-1$. This can be done by the jump transformation $F_{\alpha, \sharp}$, defined as follows:

$$
F_{\alpha, \sharp}(x)= \begin{cases}F_{\alpha}^{2}(x), & \text { if } x<0 ;  \tag{9}\\ F_{\alpha}(x), & \text { if } x \geq 0 .\end{cases}
$$

Note that the map $F_{\alpha, \sharp}$ from (9) is explicitly given by:

$$
F_{\alpha, \sharp}(x)= \begin{cases}-\frac{x}{1+2 x}, & \text { if } \alpha-1 \leq x<0  \tag{10}\\ \frac{x}{1-x}, & \text { if } 0 \leq x<\frac{1}{1+\alpha} \\ \frac{1-x}{x}, & \text { if } \frac{1}{1+\alpha} \leq x \leq \frac{1}{\alpha}\end{cases}
$$

This is well-defined for any $0<\alpha<1$. Indeed, the map $F_{\alpha, \sharp}$ from (10) skips $F_{\alpha}^{k+1}(x)$ if $F_{\alpha}^{k}(x)<0$, which implies that there exists an $n \geq$ 1 such that $G_{\alpha}^{n}(x)=F_{\alpha}^{k}(x)$ and $\varepsilon_{n}(x)=-1$. Thus we see that $\frac{p_{n}(x)-p_{n-1}(x)}{q_{n}(x)-q_{n-1}(x)}$ has been skipped in the sequence of the mediant convergents. In this note, we do not further consider this map $F_{\alpha, \sharp}$ since the discussion is almost the same as that of $F_{\alpha, b}$.

Now we consider $\frac{s_{k}(x)}{t_{k}(x)}=\Pi_{k}(x)(-\infty)$ with $s_{k}(x), t_{k}(x) \in \mathbb{Z}$, coprime, $t_{k}>0$. From this and (7) we derive that

$$
t_{k}^{2}(x)\left|x-\frac{s_{k}(x)}{t_{k}(x)}\right|=\left|F_{\alpha}^{k}(x)-\Pi_{k}^{-1}(-\infty)\right|^{-1}
$$

for $x \in\left[\alpha-1, \frac{1}{\alpha}\right]$ and $n \geq 1$. Note that $F_{\alpha}^{k}(x)$ can be interpreted as the future of $x$ at time $k$, while $\Pi_{k}^{-1}(-\infty)$ is like the past of $x$ at time $k$; see also Chapter 4 in [10]. For this reason, it is interesting to find the closure of the set

$$
\left\{\left(F_{\alpha}^{k}(x), \Pi_{k}^{-1}(x)(-\infty)\right): x \in\left[\alpha-1, \frac{1}{\alpha}\right], k>0\right\}
$$

This leads us to consider the following maps:

$$
\hat{F}_{\alpha}(x, y)= \begin{cases}\left(-\frac{x}{1+x},-\frac{y}{1+y}\right), & \text { if } \alpha-1 \leq x<0  \tag{11}\\ \left(\frac{x}{1-x}, \frac{y}{1-y}\right), & \text { if } 0 \leq x<\frac{1}{1+\alpha} \\ \left(\frac{1-x}{x}, \frac{1-y}{y}\right), & \text { if } \frac{1}{1+\alpha} \leq x<\frac{1}{\alpha}\end{cases}
$$

and

$$
\hat{F}_{\alpha, b}(x, y)= \begin{cases}\left(-\frac{1+2 x}{x},-\frac{1+2 y}{y}\right), & \text { if } \alpha-1 \leq x<-\frac{1}{2}  \tag{12}\\ \left(-\frac{x}{1+x},-\frac{y}{1+y}\right), & \text { if }-\frac{1}{2} \leq x<0 \\ \left.\frac{x}{1-x}, \frac{y}{1-y}\right), & \text { if } 0 \leq x<\frac{1}{2} \\ \left(\frac{1-2 x}{x}, \frac{1-2 y}{y}\right), & \text { if } \frac{1}{2} \leq x \leq \frac{1}{1+\alpha} \\ \left(\frac{1-x}{x}, \frac{1-y}{y}\right), & \text { if } \frac{1}{1+\alpha}<x \leq 1\end{cases}
$$

where $(x, y)$ is in a 'reasonable domain' of the definition of each map, respectively. The question is to find this 'reasonable domain' for each case. This will be done in Theorem 1 for $\hat{F}_{\alpha}$ and in Theorem 2 for $\hat{F}_{\alpha, b}$. For example, for $\hat{F}_{\alpha}$ the domain will be the closure of

$$
\left\{\left(F_{\alpha}^{k}(x),\left(A_{1}(x) \cdots A_{k}(x)\right)^{-1}(-\infty)\right): x \in\left[\alpha-1, \frac{1}{\alpha}\right], k>0\right\}
$$

so that $\hat{F}_{\alpha}$ is bijective except for a set of Lebesgue measure 0 . From this point of view, $\hat{F}_{\alpha}$ is the planar representation of the natural extension of $F_{\alpha}$ in the sense of Ergodic theory. Another point of view is that the characterization of quadratic surds by the periodicity of the map. Indeed, it is easy to see that $x \in(0,1)$ is strictly periodic by the iteration of $F$ if and only if it is a quadratic surd and its algebraic conjugate is negative. We can characterise the set of quadratic surds in a similar way with $\hat{G}_{\alpha}^{*}$, see the next section, and also $\hat{F}_{\alpha}$. We can apply the above to the construction of the natural extension of $F_{\alpha, b}$. Indeed, it is obtained as an induced transformation of $\hat{F}_{\alpha}$. In the next section, we give a direct construction of the natural extension of $\hat{F}_{\alpha}$ as a tower of the natural extension $\hat{G}_{\alpha}^{*}$ of $G_{\alpha}$.

## 3. The natural extension of $F_{\alpha}$ For $0<\alpha<\frac{1}{2}$

As the case $\frac{1}{2} \leq \alpha \leq 1$ was discussed in [31, 32], in the rest of this paper we will focus on the case $0<\alpha<\frac{1}{2}$. We give some figures in the case of $\alpha=\sqrt{2}-1$ for better understanding of the construction. We selected this value of $\alpha$ as an example as this is historically the first "more difficult" case; for $\alpha \in(\sqrt{2}-1,1]$ the natural extensions are simply connected regions which are the union of finitely many overlapping rectangles, while for $\alpha=\sqrt{2}-1$ the natural extension consists of two disjoint rectangles; see [25, 26, 17]. In [17] it is shown that for $\alpha \in\left(\frac{\sqrt{10}-3}{2}, \sqrt{2}-1\right)$ there is a countably infinite number of disjoint connected regions. For $0<\alpha<\sqrt{2}-1$ it is not so easy to
describe $\Omega_{\alpha}$ explicitly; see the discussion at the end of Section 2, and also [24, 25, 26, 17].

We start with the domain $\Omega_{\alpha}$ from [24] and the natural extension $\operatorname{map} \hat{G}_{\alpha}: \Omega_{\alpha} \rightarrow \Omega_{\alpha}$, given by

$$
(x, y) \mapsto \begin{cases}\left(-\frac{1}{x}-b, \frac{1}{-y+b}\right), & \text { for } x<0 \\ \left(\frac{1}{x}-b, \frac{1}{y+b}\right), & \text { for } x>0\end{cases}
$$

for $(x, y) \in \Omega_{\alpha}$. Next we change $y$ to $-\frac{1}{y}$, i.e., we consider

$$
\Omega_{\alpha}^{*}=\left\{(x, y):\left(x,-\frac{1}{y}\right) \in \Omega_{\alpha}\right\} ;
$$

see Figure 3, and the map $\hat{G}_{\alpha}^{*}: \Omega_{\alpha}^{*} \rightarrow \Omega_{\alpha}^{*}$, defined by:

$$
(x, y) \mapsto \begin{cases}\left(-\frac{1}{x}-b,-\frac{1}{y}-b\right), & \text { for } x<0 \\ \left(\frac{1}{x}-b, \frac{1}{y}-b\right), & \text { for } x>0,\end{cases}
$$

where $b=\left\lfloor\left|\frac{1}{x}\right|+\alpha-1\right\rfloor$; this gives another version of the natural extension, with which we work with for the rest of the paper. Recall from [24] that $\hat{G}_{\alpha}: \Omega_{\alpha} \rightarrow \Omega_{\alpha}$ (and therefore $\hat{G}_{\alpha}^{*}$ ) is bijective except for a set of Lebesgue measure 0 . The reason to move from $\Omega_{\alpha}$ to $\Omega_{\alpha}^{*}$ is that the first and second coordinate maps of $G_{\alpha}$ are similar. This allows for a more unified treatment. Also note that $\Omega_{\alpha} \subset[\alpha-1, \alpha] \times[0,1]$.

Figure 2. $\hat{\Omega}_{\alpha, k, \pm}$ for $\alpha=\sqrt{2}-1$

Figure 3. $\Omega_{\alpha}^{*}$ for $\alpha=\sqrt{2}-1$

Although formally $\alpha \notin \mathbb{I}_{\alpha}$, we define $k_{0}$ as the first digit of $\alpha$ in the $G_{\alpha}$-expansion of $\alpha$, i.e., $\frac{1}{k_{0}+\alpha} \leq \alpha<\frac{1}{k_{0}-1+\alpha}$. Furthermore, we define cylinders by

$$
\left\{\begin{array}{l}
\Omega_{\alpha, k_{0},+}^{*}=\left\{(x, y) \in \Omega_{\alpha}^{*}: \frac{1}{k_{0}+\alpha}<x<\alpha\right\}  \tag{13}\\
\Omega_{\alpha, k,+}^{*}=\left\{(x, y) \in \Omega_{\alpha}^{*}: \frac{1}{k+\alpha}<x \leq \frac{1}{(k-1)+\alpha}\right\}, \text { for } k>k_{0} \\
\Omega_{\alpha, 2,-}^{*}=\left\{(x, y) \in \Omega_{\alpha}^{*}: \alpha-1<x \leq-\frac{1}{2+\alpha}\right\}, \\
\Omega_{\alpha, k,-}^{*}=\left\{(x, y) \in \Omega_{\alpha}^{*}:-\frac{1}{(k-1)+\alpha}<x \leq-\frac{1}{k+\alpha}\right\}, \text { for } k \geq 3
\end{array}\right.
$$

Then we put

$$
\left\{\begin{array}{l}
\hat{\Omega}_{\alpha, k,-}=\left\{(x, y):\left(-\frac{1}{x},-\frac{1}{y}\right) \in \Omega_{\alpha, k,-}^{*}\right\} ; \\
\hat{\Omega}_{\alpha, k,+}=\left\{(x, y):\left(\frac{1}{x}, \frac{1}{y}\right) \in \Omega_{\alpha, k,+}^{*}\right\} .
\end{array}\right.
$$

Note that if $(x, y) \in \hat{\Omega}_{\alpha, k,-}$ we have that $x>0$ and $y \geq 0$; see Figure 2, For convenience we put $\Omega_{\alpha, k,+}^{*}=\emptyset$ for $2 \leq k<k_{0}$. It is easy to see that

$$
\Omega_{\alpha}^{*}=\left(\bigcup_{k=2}^{\infty}\left(\hat{\Omega}_{\alpha, k,-}-(k, k)\right)\right) \cup\left(\bigcup_{k=k_{0}}^{\infty}\left(\hat{\Omega}_{\alpha, k,+}-(k, k)\right)\right) \quad \text { (disj. a.e.) }
$$

where (disj. a.e.) means "disjoint except for a set of measure 0". This disjointness follows from the next lemma.

Lemma 2. For every $k \in \mathbb{N}, k \geq 2$, we have:

$$
\left(\hat{\Omega}_{\alpha, k+1,-}-(k+1, k+1)\right) \cap\left(\hat{\Omega}_{\alpha, k,+}-(k, k)\right)=\emptyset \quad \text { disj. a.e., }
$$

or equivalently,

$$
\left(\hat{\Omega}_{\alpha, k+1,-}-(1,1)\right) \cap\left(\hat{\Omega}_{\alpha, k,+}-(0,0)\right)=\emptyset \quad \text { disj. a.e. } ;
$$

see Figure 4.
Proof. We see

$$
\left(\hat{\Omega}_{\alpha, k, \pm}-(k, k)\right)=\hat{G}_{\alpha}^{*}\left(\Omega_{\alpha, k, \pm}^{*}\right) .
$$

Then the assertion follows from the a.e.-bijectivity of $\hat{G}_{\alpha}^{*}$.
For $j \geq 1$, we define

$$
\Upsilon_{\alpha, j}=\bigcup_{k=j+1}^{\infty}\left(\hat{\Omega}_{\alpha, k,-}-(k-j, k-j)\right) \cup \bigcup_{k=j+1}^{\infty}\left(\hat{\Omega}_{\alpha, k,+}-(k-j, k-j)\right)
$$

Figure 4. $\hat{\Omega}_{\alpha, k, \pm}-(1,1)$ for $\alpha=\sqrt{2}-1$
for $j \geq 2$, see Figure 5, and

$$
\Upsilon_{\alpha}=\bigcup_{j=1}^{\infty} \Upsilon_{\alpha, j} .
$$

From Lemma 2, this is "disj. a.e.". We also see

$$
\Upsilon_{\alpha, j} \cap \hat{\Omega}_{\alpha, j,+}=\emptyset \quad \text { (disj. a.e.) }
$$

which implies

$$
\Omega_{\alpha}^{*} \cap\left(\Upsilon_{\alpha}\right)^{-1}=\emptyset \quad \text { (disj. a.e.) }
$$

where $\left(\Upsilon_{\alpha}\right)^{-1}=\left\{(x, y):\left(\frac{1}{x}, \frac{1}{y}\right) \in \Upsilon_{\alpha}\right\}$. Note that $\left(\Upsilon_{\alpha}\right)^{-1} \subset\{(x, y)$ : $x>0\}$.

Now we will define the 'reasonable domain' $V_{\alpha}$ for the natural extension map $\hat{F}_{\alpha}$ from (11). We put $V_{\alpha}=\Omega_{\alpha}^{*} \cup\left(\Upsilon_{\alpha}\right)^{-1}$; see Figure 6. From the construction of $V_{\alpha}$, it is not hard to see the following result.

Theorem 1. The dynamical system $\left(V_{\alpha}, \hat{F}_{\alpha}\right)$ together with the measure $\mu_{\alpha}$ with density $\frac{d x d y}{(x-y)^{2}}$ is a representation of the natural extension of $\left(\left[\alpha-1, \frac{1}{\alpha}\right), F_{\alpha}\right)$ with measure $\nu_{\alpha}$, which is the projection of $\mu_{\alpha}$ on the first coordinate.

Proof. We show the following below. Then the assertion of the theorem is proved in exactly the same way as in [32] in the case of $\frac{1}{2} \leq \alpha \leq 1$.

Figure 5. $\hat{\Omega}_{\alpha, k, \pm}-(\ell, \ell)$ and $\Upsilon_{\alpha, k}$ for $\alpha=\sqrt{2}-1$
(1) The map $\hat{F}_{\alpha}$ defined on $V_{\alpha}$ is surjective.
(2) The map $\hat{F}_{\alpha}$ is bijective except for a set of measure 0 .
(3) The measure $\frac{d x d y}{(x-y)^{2}}$ is the absolutely continuous ergodic invariant measure.
(4) The Borel $\sigma$-algebra $\mathcal{B}\left(V_{\alpha}\right)$ on $V_{\alpha}$ satisfies:

$$
\mathcal{B}\left(V_{\alpha}\right)=\sigma\left(\bigvee_{n=0}^{\infty} \hat{F}_{\alpha}^{n} \pi_{1}^{-1} \mathcal{B}([\alpha-1, \alpha))\right),
$$

where $\mathcal{B}([\alpha-1, \alpha))$ is the Borel $\sigma$-algebra on $[\alpha-1, \alpha)$ and $\pi_{1}: V_{\alpha} \rightarrow[\alpha-1, \alpha)$ is the projection on the first coordinate.

For a.e. $(x, y) \in \Omega_{\alpha}^{*}, x \neq 0$, there exists a unique element $\left(x_{0}, y_{0}\right) \in$ $\Omega_{\alpha}^{*}$ and a positive integer $k$ such that

$$
(x, y)=\hat{G}_{\alpha}^{*}\left(x_{0}, y_{0}\right)= \begin{cases}\left(-\frac{1}{x_{0}}-k,-\frac{1}{y_{0}}-k\right), & \text { if } x_{0}<0 \\ \left(\frac{1}{x_{0}}-k, \frac{1}{y_{0}}-k\right), & \text { if } x_{0}>0\end{cases}
$$

Figure 6. $V_{\alpha}=\Omega_{\alpha}^{*} \cup\left(\Upsilon_{\alpha}\right)^{-1}$ for $\alpha=\sqrt{2}-1$
since $\left(\Omega_{\alpha}^{*}, \hat{G}_{\alpha}^{*}\right)$ is a natural extension of $\left(\mathbb{I}_{\alpha}, G_{\alpha}\right)$; see [24].
If $x_{0}<0$, then we see

$$
\left(-\frac{1}{x_{0}}-(k-1),-\frac{1}{y_{0}}-(k-1)\right) \in \Upsilon_{\alpha, 1}
$$

This implies $\alpha \leq-\frac{1}{x_{0}}-(k-1)<\alpha+1$. We put

$$
\left(x_{1}, y_{1}\right)=\left(\left(-\frac{1}{x_{0}}-(k-1)\right)^{-1},\left(-\frac{1}{y_{0}}-(k-1)\right)^{-1}\right)
$$

and have $\frac{1}{1+\alpha}<x_{1} \leq \frac{1}{\alpha}$. From (11), we have that $(x, y)=\hat{F}_{\alpha}\left(x_{1}, y_{1}\right)$. If $x_{0}>0$, then

$$
\left(\frac{1}{x_{0}}-(k-1), \frac{1}{y_{0}}-(k-1)\right) \in \Upsilon_{\alpha, 1}
$$

and $(x, y)=\hat{F}_{\alpha}\left(x_{1}, y_{1}\right)$ with

$$
\left(x_{1}, y_{1}\right)=\left(\left(\frac{1}{x_{0}}-(k-1)\right)^{-1},\left(\frac{1}{y_{0}}-(k-1)\right)^{-1}\right) .
$$

We note that in both cases we have

$$
\begin{equation*}
\left(x_{1}, y_{1}\right) \in \Upsilon_{\alpha, 1}^{-1} \subset\left(\Upsilon_{\alpha}\right)^{-1} \tag{14}
\end{equation*}
$$

Next we consider the case $(x, y) \in \Upsilon_{\alpha}^{-1}$. This means $\left(\frac{1}{x}, \frac{1}{y}\right) \in \Upsilon_{\alpha, j}$ for some $j \geq 1$. We consider two cases.

Case (a): $\left(\frac{1}{x}, \frac{1}{y}\right) \in \hat{\Omega}_{\alpha, j+1, \pm}-(1,1)$.
In this case, there exists $\left(x_{0}, y_{0}\right) \in \hat{\Omega}_{\alpha, j+1, \pm}$ such that $\left(\frac{1}{x}, \frac{1}{y}\right)=\left(x_{0}-\right.$ $\left.1, y_{0}-1\right)$. Thus $\left(x_{1}, y_{1}\right)=\left( \pm \frac{1}{x_{0}}, \pm \frac{1}{y_{0}}\right) \in \Omega_{\alpha, j+1}^{*}$, which imlies

$$
\frac{1}{j+1+\alpha}< \pm x_{1} \leq \frac{1}{j+\alpha} \leq \frac{1}{1+\alpha}
$$

Hence we find that $(x, y)=\hat{F}_{\alpha}\left(x_{1}, y_{1}\right)$. Here we see

$$
\begin{equation*}
\left(x_{1}, y_{1}\right) \in \Omega_{\alpha}^{*} . \tag{15}
\end{equation*}
$$

Case (b): $\left(\frac{1}{x}, \frac{1}{y}\right) \in \hat{\Omega}_{\alpha, k, \pm}-(k-j, k-j)$ for $k>j+1$.
In this case, we have

$$
\begin{equation*}
\left(x_{0}, y_{0}\right):=\left(\frac{1}{x}+1, \frac{1}{y}+1\right) \in \Omega_{\alpha, k \pm}-(k-j-1, k-j-1) \tag{16}
\end{equation*}
$$

and then

$$
\begin{equation*}
\left(x_{1}, y_{1}\right):=\left(\frac{1}{x_{0}}, \frac{1}{y_{0}}\right) \in \Upsilon_{\alpha}^{-1} . \tag{17}
\end{equation*}
$$

This shows

$$
(x, y)=\hat{F}_{\alpha}\left(x_{1}, y_{1}\right)
$$

Consequently, we have the first statement. The second statement follows from (14), (15), (16) and (17). The third statement is also easy to obtain. Indeed, it is well-known that the measure given here is the absolutely continuous invariant measure for the direct product of the same linear fractional transformation. Because $\hat{G}_{\alpha}^{*}$ is an induced transformation of $\hat{F}_{\alpha}$ to $\Omega_{\alpha}^{*}$, the ergodicity of $\hat{F}_{\alpha}$ follows from that of $\hat{G}_{\alpha}^{*}$. The ergodicity of the latter is equivalent to that of $G_{\alpha}$ and it was proved by L. Luzzi and S. Marmi in [25]. For the last statement, note that (6) allows one to identify a point $x$ with a one-sided sequence of matrices with entries $A^{ \pm}, A^{R}$. As a result, $F_{\alpha}, \hat{F}_{\alpha}$ can be seen as a one-sided resp. two sided shifts, from which the fourth statement follows.

Figure 7. $V_{\alpha, b}=V_{\alpha} \cap\{(x, y): x \leq 1\}$ for $\alpha=\sqrt{2}-1$
4. The natural extension of $F_{\alpha, b}$ For $0<\alpha<\frac{1}{2}$

In the case of $\alpha=1, F_{1}$ is the original Farey map $F$. We recall that

$$
\hat{F}(x, y)= \begin{cases}\left(\frac{x}{1-x}, \frac{y}{1-y}\right), & \text { if } 0 \leq x<\frac{1}{2} \\ \left(\frac{1-x}{x}, \frac{1-y}{y}\right), & \text { if } \frac{1}{2} \leq x \leq 1\end{cases}
$$

defined on $V_{1}=\{(x, y): 0 \leq x \leq 1,-\infty \leq y \leq 0\}$ is the natural extension of $F$ with the invariant measure $\hat{\mu}_{1}$ defined by $d \hat{\mu}_{1}=\frac{d x d y}{(x-y)^{2}}$. In particular, $\hat{F}$ is bijective on $V_{1}$ except for a set of Lebesgue measure 0 . It is easy to see that $F_{1}$ and $F_{1, b}$ are the same. In the case of $\frac{1}{2} \leq \alpha<1$, the complete description was given in [32]. Here we consider the case $0<\alpha<\frac{1}{2}$ as a continuation of the previous section.

We put $V_{\alpha, b}=\left\{(x, y) \in V_{\alpha}, x \leq 1\right\}$ and consider the induced transformation $\hat{F}_{\alpha, b}$ of $\hat{F}_{\alpha}$ to $V_{\alpha, b}$; see Figure 7. Recall the definition of the $\operatorname{map} \hat{F}_{\alpha, b}$, as given in (12).

Theorem 2. The dynamical system $\left(V_{\alpha, b}, \hat{F}_{\alpha, b}, \mu_{\alpha, b}\right)$ is a representation of the natural extension of $\left([\alpha-1,1], F_{\alpha, b}, \nu_{\alpha, b}\right)$. Here the invariant measure $\mu_{\alpha, b}$ has density $\frac{d x d y}{(x-y)^{2}}$ on $V_{\alpha, b}$, and $\nu_{\alpha, b}$ is the projection of $\mu_{\alpha, b}$ on the first coordinate.

Proof. Recall that $F_{\alpha, b}(x)=F_{\alpha}^{K(x)}(x)$ with $K(x)=\min \{K \geq 1$ : $\left.F_{\alpha}^{K}(x) \in[\alpha-1,1]\right\}$, and for $(x, y) \in V_{\alpha, b}$, one has $x \in[\alpha-1,1]$. Since the first coordinate of $\hat{F}_{\alpha}(x, y)$ is $F_{\alpha}(x)$, we find $\hat{F}_{\alpha, b}(x, y)=\hat{F}_{\alpha}^{K(x)}(x, y)$. Here, we note that the first coordinate is $F_{\alpha}(x)$. Because of the general fact that an induced transformation of a bijective map is bijective, we see that $\hat{F}_{\alpha, b}$ is bijective. The rest of the proof follows from a standard argument.

Put

$$
\begin{cases}D_{1}=\left(V_{\alpha,-}+(1,1)\right) & \left(\subset V_{1}\right) \\ D_{2}=V_{\alpha,+} \backslash D_{1} & \left(\subset V_{1}\right)\end{cases}
$$

with $V_{\alpha,-}=\left\{(x, y) \in V_{\alpha, b}: x<0\right\}$ and $V_{\alpha,+}=\left\{(x, y) \in V_{\alpha, b}: x \geq 0\right\}$. We write $D=D_{1} \cup D_{2}$. By the definition we see that $D \subset V_{1}$. We define $\psi: D \rightarrow V_{\alpha}$ by

$$
\psi(x, y)= \begin{cases}(x-1, y-1), & \text { if }(x, y) \in D_{1}  \tag{18}\\ (x, y), & \text { if }(x, y) \in D_{2}\end{cases}
$$

see Figure 8. We note that
(1) $D$ has positive Lebesgue measure since $V_{\alpha,-}$ has positive Lebesgue measure; see [24];
(2) $(\psi)^{-1}\left(\mu_{\alpha}\right)=\left.\mu_{1}\right|_{D}$;
(3) $\psi$ is injective.

Theorem 3. We have $D=V_{1}$ and for a.e. $(x, y) \in V_{1}$,

$$
\begin{equation*}
\left((\psi)^{-1} \circ \hat{F}_{\alpha, b} \circ \psi\right)(x, y)=\hat{F}(x, y) . \tag{19}
\end{equation*}
$$

In other words, for any $0<\alpha<\frac{1}{2}$, $\left(V_{\alpha, b}, \hat{\mu}_{\alpha, b}, \hat{F}_{\alpha, b}\right)$ is metrically isomorphic to $\left(V_{1}, \hat{\mu}_{1}, \hat{F}\right)$ by the isomorphism $\psi: V_{1} \rightarrow V_{\alpha, b}$.

Proof. We choose $(x, y) \in D$ such that both $\left\{\hat{F}^{n}(x, y): n \geq 0\right\}$ and $\left\{\hat{F}_{\alpha, b}^{n}(\psi(x, y)): n \geq 0\right\}$ are dense in $V_{1}$ and $V_{\alpha}$, respectively. This is possible due to the fact that $\hat{F}$ and $\hat{F}_{\alpha, b}$ are ergodic with respect to $\mu_{1}$ and $\mu_{\alpha}$, respectively. We see that the following hold:

Figure 8. $\psi^{-1}$ for $\alpha=\sqrt{2}-1$
(1) $\left(x_{0}, y_{0}\right)=\psi(x, y) \in V_{\alpha,-}, \alpha \leq x<\frac{1}{2}$

In this case, $F_{\alpha, b}\left(x_{0}\right)=\frac{2 x-1}{1-x}<0$ since $x_{0}<-\frac{1}{2}$. Then we see $\left(\psi^{-1} \circ \hat{F}_{\alpha, b} \circ \psi\right)(x, y)=\left(\frac{x}{1-x}, \frac{y}{1-y}\right)=\hat{F}(x, y)$.
(2) $\left(x_{0}, y_{0}\right)=\psi(x, y) \in V_{\alpha,-}, \frac{1}{2} \leq x<1$

For $F_{\alpha, b}\left(x_{0}\right)=\frac{1-x}{x}>0$, we see $\left(\psi^{-1} \circ \hat{F}_{\alpha, b} \circ \psi\right)(x, y)=\left(\frac{1-x}{x}, \frac{1-y}{y}\right)=$ $\hat{F}(x, y)$.
(3) $(x, y) \notin \psi^{-1}\left(V_{\alpha,-}\right), 0 \leq x \leq \frac{1}{2}$

In this case, $\hat{F}_{\alpha, b}(\psi(x, y))=\hat{F}_{\alpha, b}(x, y)=\left(\frac{x}{1-x}, \frac{y}{1-y}\right)$ and $\frac{x}{1-x} \geq$
0 . Thus we have $\left(\psi^{-1} \circ \hat{F}_{\alpha, b} \circ \psi\right)(x, y)=\hat{F}(x, y)$.
(4) $(x, y) \notin \psi^{-1}\left(V_{\alpha,-}\right), \frac{1}{2} \leq x \leq \frac{1}{1+\alpha}$

We see $\psi(x, y)=(x, y)$ again and $\hat{F}_{\alpha, b}(\psi(x, y))=\hat{F}_{\alpha, b}(x, y)=$

$$
\begin{aligned}
& \left(\frac{1-2 x}{x}, \frac{1-2 y}{y}\right) . \text { However, } \frac{1-2 x}{x}<0 . \text { So we have } \\
& \begin{aligned}
\left(\psi^{-1} \circ \hat{F}_{\alpha, b} \circ \psi\right)(x, y) & =\left(\frac{1-2 x}{x}+1, \frac{1-2 y}{y}+1\right) \\
& =\left(\frac{1-x}{x}, \frac{1-y}{y}\right)=\hat{F}(x, y) .
\end{aligned} .
\end{aligned}
$$

(5) $(x, y) \notin \psi^{-1}\left(V_{\alpha,-}\right), \frac{1}{1+\alpha}<x \leq 1$

In this case, we see

$$
\hat{F}_{\alpha, b}(\psi(x, y))=\hat{F}_{\alpha, b}(x, y)=\left(\frac{1-x}{x}, \frac{1-y}{y}\right)
$$

and get $\left(\psi^{-1} \circ \hat{F}_{\alpha, b} \circ \psi\right)(x, y)=\hat{F}_{\alpha, b}(x, y)$.
As a consequence, we find that $\left(\psi^{-1} \circ \hat{F}_{\alpha, b} \circ \psi\right)(x, y)=\hat{F}(x, y)$ and $\hat{F}(x, y) \in D$ for any $(x, y) \in D$. Since we have chosen $\left\{\hat{F}^{n}(x, y): n \geq\right.$ $0\}$ and $\left\{\hat{F}_{\alpha, b}^{n}(\psi(x, y)): n \geq 0\right\}$ are dense in $V_{1}$ and $V_{\alpha}$, respectively, we find that $D=V_{1}$ and $\psi(D)=V_{\alpha}$. Note that from (19) we see that $(x, y) \in \psi^{-1}\left(V_{\alpha}\right)=V_{1} \cap \psi^{-1}\left(V_{\alpha}\right)$, then $\hat{F}(x, y) \in V_{1} \cap \psi^{-1}\left(V_{\alpha}\right)$. Choose $(x, y) \in V_{1} \cap \psi^{-1}\left(V_{\alpha}\right)$ such that the orbit $\left(\hat{F}^{k}(x, y)\right)$ is dense in $V_{1}$. Let $\left(x_{0}, y_{0}\right) \in V_{1}$, then $\left(x_{0}, y_{0}\right)=\lim _{k \rightarrow \infty} \hat{F}^{n_{k}}(x, y)$ for some subsequence $\left(n_{k}\right)$. From the above, $\hat{F}^{n_{k}}(x, y) \in \psi^{-1}\left(V_{\alpha}\right)$. Since $\psi^{-1}\left(V_{\alpha}\right)$ is closed, taking limits we see that $\left(x_{0}, y_{0}\right) \in \psi^{-1}\left(V_{\alpha}\right)$. We conclude that $\psi^{-1}\left(V_{\alpha}\right)=V_{1}$. Finally we see that the choice of $(x, y)$ implies that (19) holds for a.e. $(x, y)$. This concludes the assertion of this theorem.

## 5. Some applications

As stated in the Introduction, in Section $\S 5.1$ we extend the result from [23]. That is, we show that the set of normal numbers with respect to $G_{\alpha}$ is the same with that of $G_{\alpha^{\prime}}$ for any $\alpha$ and $\alpha^{\prime}$ in $(0,1]$; see Theorem 4. To prove this result, we need the natural extensions of the $\alpha$-Farey maps. In $\S 5.2$ we extend the result of [29], by proving that for a.e. $\alpha$ in $(0,1), G_{\alpha}$ is not $\phi$-mixing; see $\S 5.2$ for the definition. To do so, we use the result of $\S 5.1$ together with a result from [8]. What we need are statements like " $G_{\alpha}^{n}(\alpha-1)$ is dense" and "there exist $n_{0}$ and $m_{0}$ such that $G_{\alpha}^{n_{0}}(\alpha-1)=G_{\alpha}^{m_{0}}(\alpha)$." The former follows from §5.1 and the latter from [8] for a.e. $\alpha$.
5.1. Normal numbers. Given any finite sequence of non-zero integers $b_{1}, b_{2}, \ldots, b_{n}$, we define the cylinder set $\left\langle b_{1}, \ldots, b_{n}\right\rangle_{\alpha}$ as

$$
\begin{equation*}
\left\langle b_{1}, \ldots, b_{n}\right\rangle_{\alpha}=\left\{x \in \mathbb{I}_{\alpha}: c_{\alpha, 1}(x)=b_{1}, \ldots, c_{\alpha, n}(x)=b_{n}\right\} \tag{20}
\end{equation*}
$$

where $c_{\alpha, j}(x)=\varepsilon_{\alpha, j}(x) a_{\alpha, j}(x)$, for $j=1,2, \ldots, n$. An irrational number $x \in \mathbb{I}_{\alpha}$ is normal with respect to $G_{\alpha}$ if for any cylinder set $\left\langle b_{1}, \ldots, b_{n}\right\rangle_{\alpha}$,

$$
\lim _{N \rightarrow \infty} \frac{\#\left\{0 \leq m \leq N-1: G_{\alpha}^{m}(x) \in\left\langle b_{1}, \ldots, b_{n}\right\rangle_{\alpha}\right\}}{N}=\mu_{\alpha}\left(\left\langle b_{1}, \ldots, b_{n}\right\rangle_{\alpha}\right)
$$

holds, where $\mu_{\alpha}$ is the absolutely continuous invariant probability measure for $G_{\alpha}$. An irrational number $x \in(0,1)$ is said to be $\alpha$-normal if either $x \in[0, \alpha)$ and $x$ is normal with respect to $G_{\alpha}$, or $x \in[\alpha, 1)$ and $x-1$ is normal with respect to $G_{\alpha}$. In the sequel, we consider $\alpha=\lim _{\epsilon \downarrow 0}(\alpha-\epsilon)$ as an element of $\mathbb{I}_{\alpha}$.

Now we extend this notion to the 2 -dimensional case. Since $\hat{G}_{\alpha}^{*}$ is bijective (a.e.), we can define $\varepsilon_{\alpha, n}$ and $a_{\alpha, n}$ for $n \leq 0$ which is defined by $\varepsilon_{\alpha, n}(x, y)=\varepsilon_{\alpha}\left({\hat{G_{\alpha}^{*}}}^{n-1}(x, y)\right)$ and $a_{\alpha, n}(x, y)=a_{\alpha}\left({\hat{G_{\alpha}^{*}}}^{n-1}(x, y)\right)$.

We can define also $c_{\alpha, j}(x, y)=\varepsilon_{\alpha, j}(x, y) a_{\alpha, j}(x, y)$. With these definitions, we extends the notion of a $(k, \ell)$-cylinder set for $-\infty<k<\ell<$ $\infty$ by:

$$
\left\langle b_{k}, b_{k+1}, \ldots, b_{\ell}\right\rangle_{\alpha,(k, \ell)}=\left\{(x, y) \in \Omega_{\alpha}^{*}: c_{\alpha, k}(x)=b_{k}, \ldots, c_{\alpha, \ell}(x)=b_{\ell}\right\} .
$$

Then we can define normality of an element $(x, y) \in \Omega_{\alpha}^{*}:(x, y)$ is said to be normal with respect to $\hat{G}_{\alpha}^{*}$ if for any sequence of integers $\left(b_{k}, b_{k+1}, \ldots, b_{\ell}\right),-\infty<k<\ell<\infty$

$$
\begin{aligned}
& \lim _{N \rightarrow \infty} \frac{1}{N} \sharp\left\{1 \leq n \leq N: c_{k+n-1}(x, y)=b_{k}, \ldots, c_{\ell+n-1}(x, y)=b_{\ell}\right\} \\
= & \hat{\mu}_{\alpha}\left(\left\langle b_{k}, b_{k+1}, \ldots, b_{\ell}\right\rangle_{\alpha,(k, \ell)}\right),
\end{aligned}
$$

where $\hat{\mu}_{\alpha}$ is the absolutely continuous invariant probability measure for $\hat{G}_{\alpha}^{*}$, satisfying $d \hat{\mu}_{\alpha}=C_{\alpha} \frac{d x d y}{(x-y)^{2}}$ with the normalising constant $C_{\alpha}$. According to this definition, it is easy to see that $(x, y)$ is normal with respect to $\hat{G}_{\alpha}^{*}$ if and only if $x$ is normal with respect to $G_{\alpha}$ (independent of the choice of $y$ ). For example, one may choose $y=-\infty$. We will show the following result.

Theorem 4. The set of $\alpha$-normal numbers is the same with that of 1-normal numbers with respect to $G=G_{1}$.

The proof for $\sqrt{2}-1 \leq \alpha<\frac{1}{2}$ is basically the same as the case $\frac{1}{2} \leq \alpha \leq 1$. In what follows, we give the proof of this theorem mainly keeping n mind the case $0<\alpha<\sqrt{2}-1$. In particular, for $0<\alpha<$ $\frac{3-\sqrt{5}}{2}$. (By [24] and [28], the size of $\Omega_{\alpha}^{*}$ with respect to the measure
$\frac{d x d y}{(x-y)^{2}}$ is equal to that of $\hat{G}_{\frac{1}{2}}^{*}$ for $\frac{3-\sqrt{5}}{2} \leq \alpha<\frac{1}{2}$ and is larger than it for $0<\alpha<\frac{3-\sqrt{5}}{2}$.)

We define an induced map $\hat{F}_{\alpha, b, 2}$ of $\hat{F}_{\alpha, b}$. To do it, first we define also an induced map $\hat{F}_{\alpha, b, 1}$. Here the domains of maps are $V_{\alpha, b, 1}$ and $V_{\alpha, b, 2}$, $V_{\alpha, b, 1} \supset V_{\alpha, b, 2}$. We put

$$
\begin{equation*}
V_{\alpha, b, 1}=\Omega_{\alpha}^{*} \cup\left\{\left(-\frac{x}{1+x},-\frac{y}{1+y}\right):(x, y) \in \Omega_{\alpha}^{*},-\frac{1}{2} \leq x<0\right\} . \tag{21}
\end{equation*}
$$

We note that the second part of the right side is

$$
\left\{(x, y): x \leq 1,\left(\frac{1}{x}, \frac{1}{y}\right) \in \cup_{k=2}^{\infty} \hat{\Omega}_{\alpha, k,-}-(1,1)\right\} .
$$

Hence we see $V_{\alpha, b, 1}=V_{\alpha, b} \cap\{(x, y): y \leq-1\}$. Then $\hat{F}_{\alpha, b, 1}$ is the induced map of $\hat{F}_{\alpha, b}$ to $\hat{V}_{\alpha, b, 1}$. We will write it explicitly. Recall the definition of $\hat{\Omega}_{\alpha, k, \pm}$, (13).
(1) If $\alpha-1 \leq x<-\frac{1}{2}$, then $\hat{F}_{\alpha, b}(x, y) \in \Omega_{\alpha}^{*} \subset V_{\alpha, b, 1}$, see (21), and $\hat{F}_{\alpha, b, 1}(x, y)=\hat{F}_{\alpha, b}(x, y)=\hat{G}_{\alpha}^{*}(x, y)$.
(2) If $-\frac{1}{2} \leq x<0$, then $\hat{F}_{\alpha}(x, y)=\left(-\frac{x}{1+x},-\frac{y}{1+y}\right)$ which implies $0<-\frac{x}{1+x} \leq 1$ and $-\frac{y}{1+y} \leq-1$. Thus we have $\hat{F}_{\alpha, b, 1}(x, y)=$ $\hat{F}_{\alpha, b}(x, y)$.
(3) If $(x, y) \in \Omega_{\alpha, k,+}^{*}$ for some $k \geq k_{0}$, then $\hat{F}_{\alpha}(x, y)=\left(\frac{x}{1-x}, \frac{y}{1-y}\right) \in$ $\hat{\Omega}_{\alpha, k,+}$. This shows $\frac{x}{1-x}<1$ but $\frac{y}{1-y}>1$. Hence $\hat{F}_{\alpha}(x, y) \notin$ $V_{\alpha, b, 1}$. The same hold for $\hat{F}_{\alpha}^{\ell}(x, y)$ for $2 \leq \ell \leq k-1$ and then $\hat{F}_{\alpha}^{k}(x, y)\left(=\hat{G}_{\alpha}^{*}(x, y)\right) \in \Omega_{\alpha}^{*} \subset V_{\alpha, b, 1}$.
(4) If $0 \leq x \leq 1,\left(\frac{1}{x}, \frac{1}{y}\right) \in \hat{\Omega}_{\alpha, k,-}-(1,1)$, then $\left(\frac{1}{x}, \frac{1}{y}\right)-(\ell, \ell) \in$ $\hat{\Omega}_{\alpha, k,-}-(\ell-1, \ell-1)=:\left(u_{\ell}, v_{\ell}\right)$ for $2 \leq \ell \leq k-1$. This implies $0>-\frac{1}{v_{\ell}}>-1$ and so $\left(\frac{1}{u_{\ell}}, \frac{1}{v_{\ell}}\right) \in V_{\alpha, b, 1}$. Moreover, $u_{k-1}^{-1} \in \mathbb{I}_{\alpha}$, where $\left(\frac{1}{x}, \frac{1}{y}\right)-(k-1, k-1)=\left(u_{k}, v_{k}\right)$. In other words, there exists $\left(u^{\prime}, v^{\prime}\right) \in \Omega_{\alpha}^{*}$ such that $\left(\frac{1}{u^{\prime}}, \frac{1}{v^{\prime}}\right)-(k, k)=$ $\left(\frac{1}{x}, \frac{1}{y}\right)-(k-1, k-1)$. Hence we have

$$
\hat{F}_{\alpha, b, 1}(x, y)=\left(\frac{1}{x}-(k-1), \frac{1}{y}-(k-1)\right)\left(=\hat{G}_{\alpha}^{*}\left(u^{\prime}, v^{\prime}\right)\right) .
$$

Consequently, we see that $\hat{F}_{\alpha, b, 1}(x, y)$ satisfies:

$$
\begin{cases}\hat{F}_{\alpha, b}(x, y)=G_{\alpha}^{*}(x, y), & \text { if } \alpha-1 \leq x<-\frac{1}{2}  \tag{22}\\ \hat{F}_{\alpha, b}(x, y), & \text { if }-\frac{1}{2} \leq x<0 \\ \hat{G}_{\alpha}^{*}(x, y), & \text { if } 0 \leq x \text { and }(x, y) \in \Omega_{\alpha}^{*} \\ \left(\frac{1}{x}-(k-1), \frac{1}{y}-(k-1)\right), & \text { if } 0 \leq x \leq 1, \text { and } \\ & \left(\frac{1}{x}, \frac{1}{y}\right) \in \hat{\Omega}_{\alpha, k,-}-(1,1)\end{cases}
$$

Next we consider $V_{\alpha, b, 2} \subset V_{\alpha, b, 1}$, which is defined as follows: $V_{\alpha, b, 2}=$ $V_{\alpha, b,-} \cup V_{\alpha, b,+}$, with

$$
\left\{\begin{aligned}
V_{\alpha, b,-} & =V_{\alpha, b, 1} \cap\{(x, y): x<0, y \leq-2\} \\
& =\Omega_{\alpha}^{*} \cap\{(x, y): x<0, y \leq-2\} \\
& \\
V_{\alpha, b,+} & =V_{\alpha, b, 1} \cap\{(x, y): x \geq 0\} .
\end{aligned}\right.
$$

Then we see that $V_{1, \mathrm{~b}, 2}=V_{1, \mathrm{~b},+}=W$, where $W$ is defined as

$$
\begin{equation*}
W=[0,1] \times[\infty,-1] \tag{23}
\end{equation*}
$$

and $V_{\alpha, b,-}=\emptyset$. Recall the map $\psi$ as defined in (18), and notice that when $\psi^{-1}$ is restricted to $V_{\alpha, b, 2}$, one finds:

$$
\psi^{-1}(x, y)= \begin{cases}(x+1, y+1) & \text { if } \quad(x, y) \in V_{\alpha, b,-} ; \\ (x, y) & \text { if }(x, y) \in V_{\alpha, b,+}\end{cases}
$$

Then from Theorem 3, we have $\psi^{-1}\left(V_{\alpha, b, 2}\right)=W$, with $W$ from (23).
Theorem 5. The induced map $\hat{F}_{\alpha, b, 2}$ of $\hat{F}_{\alpha, b, 1}$ to $V_{\alpha, b, 2}$ is metrically isomorphic to the natural extension of the Gauss map $G_{1}$, where the absolutely continuous invariant probability measure for $\hat{F}_{\alpha, b, 2}$ is given by $C_{\alpha, b, 2} \frac{d x d y}{(x-y)^{2}}$, with the normalising constant $C_{\alpha, b, 2}$, see Figures 7, (9, and Figure 8.

Proof. It is easy to see that the induced map of $\hat{F}_{1}$ on $W$ is the natural extension of the Gauss map $G$. Indeed we see, with $W$ from (23), that $\hat{G}^{*}=\left.\hat{F}_{1}\right|_{W}:$

$$
(x, y) \mapsto\left(\frac{1}{x}-\left\lfloor\frac{1}{x}\right\rfloor, \frac{1}{y}-\left\lfloor\frac{1}{x}\right\rfloor\right)
$$

is bijective on $W$ on (a.e.). Since $\psi^{-1} V_{\alpha, b, 2}=W$, the conjugacy $\psi^{-1} \circ$ $\hat{F}_{\alpha, b, 2} \circ \psi=\hat{G}_{1}^{*}$ follows from Theorem 3 and basic fact on induced transformations from Ergodic theory.

Figure 9. $V_{\alpha, b, 1}$ and $V_{\alpha, b, 2}$ for $\alpha=\sqrt{2}-1$
The next step is the definition of normal numbers associated both with $\hat{F}_{\alpha, b, 1}$ and $\hat{F}_{\alpha, b, 2}$.

We define a digit function $\delta(x, y)$ and get a sequence $\left(\delta_{n}(x, y): n \geq\right.$ $1)$ in the following way:

$$
\delta(x, y)= \begin{cases}\delta_{-, k} & \operatorname{if}(x, y) \in \Omega_{\alpha, k,-}^{*}, k \geq 2  \tag{24}\\ \delta_{+, k} & \operatorname{if}(x, y) \in \Omega_{\alpha, k,+}^{*}, k \geq k_{0} \\ \delta_{0,2} & \operatorname{if}(x, y) \in\left\{(x, y):\left(\frac{1}{x}, \frac{1}{y}\right) \in \hat{\Omega}_{\alpha, 2,-}-(1,1), x \leq 1\right\} \\ \delta_{0, k} & \operatorname{if}(x, y) \in\left\{(x, y):\left(\frac{1}{x}, \frac{1}{y}\right) \in \hat{\Omega}_{\alpha, k,-}-(1,1)\right\}, k>2\end{cases}
$$

and $\delta_{n}(x, y)=\delta\left(\hat{F}_{\alpha, b, 1}^{n-1}(x, y)\right), n \geq 1$, for $(x, y) \in V_{\alpha, b, 1}$. It is easy to see that the set of sequences $\left(\delta_{n}(x, y)\right)$ separates points of $V_{\alpha, b, 1}$.

Let ( $e_{n}: 1 \leq n \leq \ell$ ) be a block of $\delta_{j, k}$ 's. Then we define a cylinder set of length $\ell \geq 1$ by

$$
\left\langle e_{1}, e_{2}, \ldots, e_{\ell}\right\rangle_{\alpha, b, 1}=\left\{(x, y) \in V_{\alpha, b, 1}: \delta_{n}(x, y)=e_{n}, 1 \leq n \leq \ell\right\} .
$$

We denote by $\mu_{\alpha, b, 1}$ the absolutely continuous invariant probability measure for $\hat{F}_{\alpha, b, 1}$. An element $(x, y) \in V_{\alpha, b, 1}$ is said to be $\alpha$-1-Farey normal if

$$
\begin{align*}
\lim _{N \rightarrow \infty} & \frac{1}{N} \sharp\left\{n: 1 \leq n \leq N, \hat{F}_{\alpha, b, 1}^{n-1}(x, y) \in\left\langle e_{1}, e_{2}, \ldots, e_{\ell}\right\rangle_{\alpha, b, 1}\right\} \\
& =\mu_{\alpha, b, 1}\left(\left\langle e_{1}, e_{2}, \ldots, e_{\ell}\right\rangle_{\alpha, b, 1}\right) \tag{25}
\end{align*}
$$

holds for every cylinder set of length $\ell \geq 1$. We can define the notion of the $\alpha$-2-Farey normality in a similar way, compare (25) and (26).

We may use the same notation $\delta(x, y)$ restricted on $V_{\alpha, b, 2}$; c.f. (24). However, we use $\eta(x, y)$ to describe the difference between $\hat{F}_{\alpha, b, 1}$ and $\hat{F}_{\alpha, b, 2}$ : from a digit function $\eta(x, y)$ we get a sequence $\left(\eta_{n}(x, y): n \geq 1\right)$ as follows.

$$
\eta(x, y)= \begin{cases}\delta_{-, k} & \text { if } \quad(x, y) \in \Omega_{\alpha, k,-}^{*}, k \geq 2, y \leq-2 \\ \delta_{+, k} & \text { if } \quad(x, y) \in \Omega_{\alpha, k+}^{*}, k \geq k_{0} \\ \delta_{0,2} & \text { if } \quad(x, y) \in\left\{\left(\frac{1}{x}, \frac{1}{y}\right) \in \Omega_{\alpha, 2,-}^{*}-(1,1), x \leq 1\right\} \\ \delta_{0, k} & \text { if } \quad(x, y) \in\left\{\left(\frac{1}{x}, \frac{1}{y}\right) \in \Omega_{\alpha, k,-}^{*}-(1,1)\right\}, k>2\end{cases}
$$

and $\eta_{n}(x, y)=\eta\left(\hat{F}_{\alpha, b, 2}^{n-1}(x, y)\right), n \geq 1$, for $(x, y) \in V_{\alpha, b, 2}$. It is easy to see that the set of sequences $\left(\eta_{n}(x, y)\right)$ separates points of $V_{\alpha, b, 2}$.

Let $\left(e_{n}: 1 \leq n \leq \ell\right)$ be a block $\delta_{j, k}$ 's, then we define a cylinder set of length $\ell \geq 1$ by

$$
\left\langle e_{1}, e_{2}, \ldots, e_{\ell}\right\rangle_{\alpha, b, 2}=\left\{(x, y) \in V_{\alpha, b, 2}: \eta_{n}(x, y)=e_{n}, 1 \leq n \leq \ell\right\}
$$

We denote by $\mu_{\alpha, b, 2}$ the absolutely continuous invariant probability measure for $\hat{F}_{\alpha, b, 2}$. An element $(x, y) \in V_{\alpha, b, 2}$ is said to be $\alpha$-2-Farey normal if

$$
\begin{align*}
\lim _{N \rightarrow \infty} & \frac{1}{N} \sharp\left\{n: 1 \leq n \leq N, \hat{F}_{\alpha, b, 2}^{n-1}(x, y) \in\left\langle e_{1}, e_{2}, \ldots, e_{\ell}\right\rangle_{\alpha, b, 2}\right\} \\
& =\mu_{\alpha, b, 2}\left(\left\langle e_{1}, e_{2}, \ldots, e_{\ell}\right\rangle_{\alpha, b, 2}\right) \tag{26}
\end{align*}
$$

holds for every cylinder set of length $\ell \geq 1$. Here we have to be careful with the measures $\mu_{\alpha, b, 1}$ and $\mu_{\alpha, b, 2}$, which take different values only by the normalising constants for any measurable set $A \subset V_{\alpha, b, 2}$.

The proof of Theorem 4 is done in steps. We first prove that under the induced transformation $\hat{F}_{\alpha, b, 1}, \alpha$-1-Farey normality is equivalent to $\alpha$-normality. After that we proceed to the induced system $\hat{F}_{\alpha, b, 2}$, that is isomorphic to the Gauss map $\hat{G}_{1}$, and show that $\alpha$-2-Farey normality is equivalent to normality w.r.t. $\hat{G}_{1}$. On the other hand, one can prove that for points in the domain of the $\hat{F}_{\alpha, b, 2}$ map, a point is $\alpha$-1-Farey normal if and only if it is $\alpha$-2-Farey normal. From the above equivalences, one then concludes that $\alpha$-normality is equivalent to 1-normality.

Define $r_{1}:=1$ and set for $j \geq 2, r_{j}=r_{j}(x, y):=n$ whenever $\hat{F}_{\alpha, b, 1}^{n-1}(x, y) \in \Omega_{\alpha}^{*}$ and $\hat{F}_{\alpha, b, 1}^{m}(x, y) \notin \Omega_{\alpha}^{*}, r_{j-1} \leq m<n$.
Lemma 3. Suppose that

$$
(x, y) \in\left\{(x, y): x \leq 1,\left(\frac{1}{x}, \frac{1}{y}\right) \in \bigcup_{k=2}^{\infty} \hat{\Omega}_{\alpha, k,-}-(1,1)\right\}
$$

Then $(x, y)$ is $\alpha$-1-Farey normal if and only if $\hat{F}_{\alpha, b, 1}(x, y) \in \Omega_{\alpha}^{*}$ is $\alpha$-1Farey normal.

Proof. From the 4th line of the right side of (22), we have $\hat{F}_{\alpha, b, 1}(x, y) \in$ $\Omega_{\alpha}^{*}$. Then the equivalence of the normality is easy to follow.

From this lemma, it is enough to restrict the $\alpha$-1-Farey normality only for $(x, y) \in \Omega_{\alpha}^{*}$.

Lemma 4. An element $\left(x_{0}, y_{0}\right) \in \Omega_{\alpha}^{*}$ is $\alpha$-1-Farey normal if and only if $x_{0}$ is $\alpha$-normal.

Proof. Suppose that $r_{i}=r_{i}\left(x_{0}, y_{0}\right)$, and decompose $\mathbb{N}$ as $\mathbb{N}_{1} \cup \mathbb{N}_{2}$ with

$$
\mathbb{N}_{1}=\left\{r_{i}: i \geq 1\right\}\left(=\left\{n \in \mathbb{N}: \delta_{n}\left(x_{0}, y_{0}\right)=\delta_{ \pm, k} \text { for some } k\right\}\right),
$$

and

$$
\mathbb{N}_{2}=\mathbb{N} \backslash \mathbb{N}_{1}=\left\{n \in \mathbb{N}: \delta_{n}\left(x_{0}, y_{0}\right)=\delta_{0, k} \text { for some } k\right\},
$$

which corresponds to

$$
\hat{F}_{\alpha, b, 1}^{n-1}\left(x_{0}, y_{0}\right) \in \Omega_{\alpha}^{*} \text { if } n \in \mathbb{N}_{1}
$$

and

$$
\hat{F}_{\alpha, b, 1}^{n-1}\left(x_{0}, y_{0}\right) \in\left\{(x, y):\left(\frac{1}{x}, \frac{1}{y}\right) \in \cup_{k=2}^{\infty} \hat{\Omega}_{\alpha, k,-}-(1,1)\right\} \text { if } n \in \mathbb{N}_{2} .
$$

Remark 3. We easily find that the following properties hold:
(i) $\hat{F}_{\alpha, b, 1}\left(\left\langle\delta_{-, 2}\right\rangle_{\alpha, b, 1} \cap\left\{(x, y):-\frac{1}{2} \leq x<0\right\}\right)=\left\langle\delta_{0,2}\right\rangle_{\alpha, b, 1}$;
(ii) $\hat{F}_{\alpha, b, 1}\left(\left\langle\delta_{-, 2}\right\rangle_{\alpha, b, 1} \cap\left\{(x, y): \alpha-1 \leq x<-\frac{1}{2}\right\}\right)=\left\langle\delta_{-, k}\right\rangle_{\alpha, b, 1}$, for some $k \geq 2$;
(iii) $\hat{F}_{\alpha, b, 1}\left(\left\langle\delta_{-, k}\right\rangle_{\alpha, b, 1}\right)=\left\langle\delta_{0, k}\right\rangle_{\alpha, b, 1}$, for $k \geq 3$;
(iv) $\hat{F}_{\alpha, b, 1}\left(\left\langle\delta_{+, k}\right\rangle_{\alpha, b, 1}\right) \subset \Omega_{\alpha}^{*}$.

Furthermore, if $n \in \mathbb{N}_{1}$ and either $\delta_{n}\left(x_{0}, y_{0}\right)=\delta_{-, k}, k \geq 3$, or $\delta_{n}\left(x_{0}, y_{0}\right)=\delta_{-, 2}$ and the first coordinate of $\hat{F}_{\alpha, b, 1}^{n-1}\left(x_{0}, y_{0}\right)$ is in $\left(-\frac{1}{2}, 0\right)$, then $n+1 \in \mathbb{N}_{2}$ and $n+2 \in \mathbb{N}_{1}$. Otherwise $n+1 \in \mathbb{N}_{1}$.

We note that $r_{k+1}-r_{k}=1$ or 2 for any $k \geq 1$. Moreover, if $\delta_{n+1}\left(x_{0}, y_{0}\right)=\delta_{0, k}$ then $\delta_{n}\left(x_{0}, y_{0}\right)=\delta_{-, k}$.

The properties from Remark 3 show that we can reproduce $\left(\delta_{n}\left(x_{0}, y_{0}\right)\right.$ : $j \geq 1)$ if $\left(c_{j}: j \geq 1\right)$ is given as a sequence of integers, or equivalently, $\left(\delta_{r_{j}}\left(x_{0}, y_{0}\right): j \geq 1\right)$; c.f. (20). Indeed, for $(x, y) \in \Omega_{\alpha}^{*}$ we see the
following:

$$
\begin{align*}
\delta_{n}(x, y)=\delta_{-, k} & \Longleftrightarrow \quad \delta_{n+1}(x, y)=\delta_{0, k} \text { if } k \geq 3 \\
\delta_{n}(x, y)=\delta_{-, 2} & \Rightarrow\left\{\begin{array}{c}
\delta_{n+1}(x, y)=\delta_{0,2}, \\
\text { and } \delta_{n+2}(x, y)=\delta_{+, k}, k \geq k_{0} \\
\text { or } \\
\delta_{n+1}(x, y)=\delta_{-, k}, k \geq 2
\end{array}\right. \tag{27}
\end{align*}
$$

and for $\ell \geq k_{0}$,

$$
\delta_{n}(x, y)=\delta_{+, \ell} \Rightarrow\left\{\begin{array}{c}
\delta_{n+1}(x, y)=\delta_{+, k} k \geq k_{0}  \tag{28}\\
\text { or } \\
\delta_{n+1}(x, y)=\delta_{-, k} k \geq 2
\end{array}\right.
$$

So for any $(x, y) \in \Omega_{\alpha}^{*}$, from (27) and (28), we have

$$
\begin{aligned}
& \delta_{n}(x, y)=\delta_{0, k} \Rightarrow \delta_{n-1}(x, y)=\delta\left(\hat{F}_{\alpha, b, 1}^{-1}(x, y)\right)=\delta_{-, k} \text { if } k \geq 3 \\
& \delta_{n}(x, y)=\delta_{0,2} \Rightarrow \delta_{n-1}(x, y)=\delta_{-, 2} \text { and } \delta_{n+1}(x, y)=\delta_{+, \ell}, \ell \geq k_{0}
\end{aligned}
$$

Let $\left(b_{i}: 1 \leq i \leq n\right)($ see (20)) be a sequence of non-zero integers such that $\left\langle b_{1}, b_{2}, \ldots, b_{n}\right\rangle_{\alpha} \neq \emptyset$. From the above discussion, if $\left(x_{0}, y_{0}\right) \in$ $\left\langle b_{1}, b_{2}, \ldots, b_{n}\right\rangle_{\alpha}$, we can construct a sequence $\left(\hat{\delta}_{1}, \hat{\delta}_{2}, \ldots, \hat{\delta}_{m}\right)$ satisfying $\hat{\delta}_{r_{i}}=b_{i}$, where $r_{i}$ is the $i$ th occurrence of the form $\delta_{ \pm, k}$ with $r_{1}=1$ (since we start in $\hat{\Omega}_{\alpha}^{*}$ ) and $r_{n}=m$ or $m-1$, and such that $\left(x_{0}, y_{0}\right) \in$ $\left\langle\hat{\delta}_{1}, \ldots, \hat{\delta}_{m}\right\rangle_{\alpha, b, 1}$. The latter happens when $\hat{\delta}_{m}=\delta_{0,2}$. Similarly, we can construct $\left(b_{1}, b_{2}, \ldots, b_{n}\right)$ from $\left(\hat{\delta}_{1}, \hat{\delta}_{2}, \ldots, \hat{\delta}_{m}\right)$, where $b_{n}=\hat{\delta}_{m}$ or $b_{n}=\hat{\delta}_{m-1}$.

To show the statement of the lemma, first we assume that $\left(x_{0}, y_{0}\right)$ is $\alpha$-1-Farey normal. It is easy to see that:

$$
\begin{align*}
\lim _{N \rightarrow \infty} & \frac{1}{N} \sharp\left\{n: 1 \leq n \leq N, n \in \mathbb{N}_{2}\right\}=\lim _{K \rightarrow \infty} \mu_{\alpha, b, 1}\left(\cup_{k=2}^{K}\left\langle\delta_{0, k}\right\rangle_{\alpha, b, 1}\right) \\
& =\mu_{\alpha, b, 1}\left(\cup_{k=2}^{\infty}\left\langle\delta_{0, k}\right\rangle_{\alpha, b, 1}\right) . \tag{29}
\end{align*}
$$

The equality (29) also shows that

$$
\begin{equation*}
\lim _{N \rightarrow \infty} \frac{1}{N} \sharp\left\{n: 1 \leq n \leq N, n \in \mathbb{N}_{1}\right\}=\mu_{\alpha, b, 1}\left(\hat{\Omega}_{\alpha}^{*}\right), \tag{30}
\end{equation*}
$$

By the same argument, we can show that for any sequence $\left(\hat{\delta}_{1}, \ldots, \hat{\delta}_{m}\right)$,

$$
\mu_{\alpha, b, 1}\left(\left\langle\hat{\delta}_{1}, \hat{\delta}_{2}, \ldots, \hat{\delta}_{m}\right\rangle_{\alpha, b, 1}\right)=\mu_{\alpha, b, 1}\left(\left\langle b_{1}, b_{2}, \ldots, b_{n}\right\rangle_{\alpha}\right)
$$

if $\hat{\delta}_{m}$ is of the form $\delta_{ \pm, k}$, otherwise

$$
\mu_{\alpha, b, 1}\left(\left\langle\hat{\delta}_{1}, \hat{\delta}_{2}, \ldots, \hat{\delta}_{m}\right\rangle_{\alpha, b, 1}\right)=\sum_{\ell_{0}}^{\infty} \mu_{\alpha, b, 1}\left(\left\langle b_{1}, b_{2}, \ldots, b_{n}, \ell\right\rangle_{\alpha}\right) .
$$

We have

$$
\begin{align*}
& \frac{1}{N} \sharp\left\{j: 1 \leq k \leq N, \delta_{j}=b_{1}, \delta_{j+1}=b_{2}, \ldots, \delta_{n}=b_{n}\right\} \\
= & \frac{\hat{N}}{N} \frac{1}{\hat{N}} \sharp\left\{j: 1 \leq j \leq \hat{N}, c_{j}=b_{1}, c_{j+1}=b_{2}, \ldots, c_{j+n-1}=b_{n}\right\} \tag{31}
\end{align*}
$$

where $\hat{N}=\max \left\{j: r_{j} \leq N\right\}$ and $c_{j}=\varepsilon_{j}\left(x_{0} \cdot a_{j}\left(x_{0}\right)\right.$.
With this notation, the left side converges to $\mu_{\alpha, b, 1}\left(\left\langle\hat{\delta}_{1}, \ldots, \hat{\delta}_{m}\right\rangle_{\alpha, b, 1}\right)$ and the first term of the right side goes to $\hat{\mu}_{\alpha, b, 1}\left(\Omega_{\alpha}^{*}\right)$ (see (30)). Thus the second term of the right side goes to

$$
\frac{\mu_{\alpha, b, 1}\left(\left\langle\hat{\delta}_{1}, \hat{\delta}_{2}, \ldots, \hat{\delta}_{m}\right\rangle_{\alpha, b, 1}\right)}{\mu_{\alpha, b, 1}\left(\Omega_{\alpha}^{*}\right)}
$$

as $N \rightarrow \infty$ and its numerator is

$$
\mu_{\alpha, b, 1}\left(\left\{(x, y): c_{r_{1}}(c, y)=b_{1}, c_{r_{2}}(x, y)=b_{2}, \ldots, c_{r_{n}}(x, y)=b_{n}\right\}\right.
$$

The definition of $\mu_{\alpha}$ and $\mu_{\alpha, b, 1}$ implies that $\frac{1}{\mu_{\alpha, b, 1}\left(\hat{\left.\Omega_{\alpha}^{*}\right)}\right.}$ changes $\mu_{\alpha, b, 1}$ to $\mu_{\alpha}$. Consequently, we get the limit of the second term as $\mu_{\alpha}\left(\left\langle b_{1}, b_{2}, \ldots, b_{n}\right\rangle_{\alpha}\right)$. This shows that $\left(x_{0}, y_{0}\right)$ is normal with respect to $\hat{G}_{\alpha}^{*}$, which implies the $\alpha$-normality of $x_{0}$.

Next we suppose that $\left(x_{0}, y_{0}\right)$ is not $\alpha-1$-Farey normal. We want to show that $\left(x_{0}, y_{0}\right)$ is also not $\alpha$-normal. We check the equality (30) again. If $\frac{\hat{N}}{N}$ does not conveges to $\mu_{\alpha, b, 1}\left(\Omega_{\alpha}^{*}\right)$, then it is easy to see that $x_{0}$ is not $\alpha$-normal. On the other hand if $\lim _{N \rightarrow \infty} \frac{\hat{N}}{N}=\mu_{\alpha, b, 1}\left(\Omega_{\alpha}^{*}\right)$, then, by the same argument, we see that the second term of the right side of (31) does not converge to $\mu_{\alpha}\left(\left\langle b_{1}, b_{2}, \ldots, b_{n}\right\rangle_{\alpha}\right)$, which shows that $x_{0}$ is not $\alpha$-normal. Indeed, from Remark 3 we can construct a sequence $\left(\hat{\delta}_{1}, \hat{\delta}_{2}, \ldots, \hat{\delta}_{m}\right)$ such that $\hat{\delta}_{r_{j}}=\delta_{\operatorname{sgn}\left(b_{j}\right),\left|b_{j}\right|}$ and $m=r_{J}=\hat{N}$, i.e., $\hat{\delta}_{r_{j}}=\delta_{\mathrm{sgn},\left|b_{j}\right|}, 1 \leq j \leq J$ and for other $\ell\left(\ell \neq r_{j}, 1 \leq j \leq J\right)$ are of the form $\delta_{0, k}$, and it is determined uniquely by $\hat{\delta}_{\ell-1}$ since $\ell-1$ is $r_{j}$ for some $1 \leq j \leq J$. Indeed, $\hat{\delta}_{\ell}=\delta_{0, k}$ implies $\hat{\delta}_{\ell-1}=\delta_{-, k}$. Note that $\hat{\delta}_{\ell-1}=\delta_{-, 2}$ does not mean $\hat{\delta}_{\ell}=\delta_{0,2}$ since $\ell-1=r_{j}, \ell=r_{j+1}$ can happen. But $\hat{\delta}_{\ell-1}=\delta_{-, k}, k \geq 3$, implies $r_{j}+1 \neq r_{j+1}$. Then we can show the estimate in the above.

The same idea shows that the $\alpha$-1-Farey normality is equivalent to the $\alpha$-2-Farey normality. Here we note that $\hat{F}_{\alpha, b, 2}$ is an induced map of $\hat{F}_{\alpha, b, 1}$ and for $(x, y) \in V_{\alpha, b, 2}, \eta_{n}(x, y) \eta_{n+1}(x, y) \neq \delta_{-, 2} \delta_{0,2}$. So in the $\eta$-code of a point $(x, y)$ the digit $\delta_{0,2}$ serves as a marker for the missing preceding digit $\delta_{-, 2}$ in the corresponding $\delta$-code of $(x, y)$.

Lemma 5. An element $(x, y) \in \Omega_{\alpha}^{*}$ is $\alpha$-2-Farey normal if and only if it is $\alpha$-1-Farey normal.

Sketch of the proof. From the sequence $\delta_{n}(x, y)$, we can construct $\eta_{m}(x, y) \in V_{\alpha, b, 2}$ by deleting the digit $\delta_{-, 2}$ that is followed by a digit $\delta_{0,2}$. More precisely,

$$
\begin{aligned}
& \delta_{n-1}(x, y), \delta_{n}(x, y)=\delta_{-, 2}, \delta_{n+1}\left((x, y)=\delta_{0,-2}\right. \\
\Rightarrow \quad & \eta_{m}=\delta_{n-1}(x, y), \eta_{m+1}(x, y)=\delta_{n+1},
\end{aligned}
$$

where $m$ is the cardinality of $n$ such that $\delta_{n} \delta_{n+1}=\delta_{-, 2} \delta_{0,2}$. On the other hand, given the sequence $\left(\eta_{m}(x, y):-\infty<m<\infty\right)$, we can construct the sequence $\left(\delta_{n}(x, y):-\infty<n<\infty\right)$ by inserting $\delta_{-, 2}$ before every occurrence of every $\delta_{0,2}$. Following the proof of Lemma 4 , we get the result.

Lemma 6. An element $\left(x_{0}, y_{0}\right) \in \Omega_{\alpha}^{*}$ is $\alpha$-2-normal if and only if $\psi^{-1}\left(x_{0}, y_{0}\right) \in W$ is normal with respect to $\hat{G}^{*}$.

Proof. Following the above proofs, cylinder sets associated with $\hat{F}_{\alpha, b, 2}$ are approximated by each other (using $\psi$ and $\psi^{-1}$ ); see Theorem 5 Suppose that $\left(x_{0}, y_{0}\right)$ is $\alpha$-2-Farey normal. Every cylinder set associated with $\hat{G}^{*}\left(=\hat{G}_{1}^{*}\right)$ is a rectangle. To be more precise, a cylinder set $\left\langle a_{1}, a_{2}, \ldots, a_{n}\right\rangle_{1}$ is of the form $\left[\frac{p_{n}}{q_{n}}, \frac{p_{n}+p_{n-1}}{q_{n}+q_{n-1}}\right) \times[-\infty,-1]$, or $\left(\frac{p_{n}+p_{n-1}}{q_{n}+q_{n-1}}, \frac{p_{n}}{q_{n}}\right] \times[-\infty,-1]$. We divide it into three parts such that $\eta_{1}(x, y)=\delta_{\sharp, k}, \sharp=+, 0$, and - . Then $\psi^{-1}$-image of each part is a countable union of $\hat{F}_{\alpha, b, 2}$ cylinder sets, just as discussed in the above. Hence we can prove that $\left(x_{0}, y_{0}\right)$ (or $\left(x_{0}+1, y_{0}+1\right)$ is normal with respect to $\hat{G}^{*}$ in the same way.

Now suppose that $\left(x_{0}, y_{0}\right)$ is not $\alpha$-2-normal and $\psi^{-1}\left(x_{0}, y_{0}\right)$ is normal with respect to $\hat{G}^{*}$. Then there exist $\epsilon>0$ and a cylinder set with respect to $\hat{F}_{\alpha, b, 2}$ such that either

$$
\begin{align*}
\lim _{N \rightarrow \infty} & \frac{1}{N} \#\left\{n: 0 \leq m \leq N-1, \hat{F}_{\alpha, b, 2}^{m}\left(x_{0}, y_{0}\right) \in\left\langle e_{1}, e_{2}, \ldots, e_{\ell}\right\rangle_{\alpha, b, 2}\right\} \\
& >\mu_{\alpha, b, 2}\left(\left\langle e_{1}, e_{2}, \ldots, e_{\ell}\right\rangle_{\alpha, b, 2}\right)+\epsilon, \tag{32}
\end{align*}
$$

or

$$
\begin{align*}
\lim _{N \rightarrow \infty} & \frac{1}{N} \#\left\{n: 0 \leq m \leq N-1, \hat{F}_{\alpha, b, 2}^{m}\left(x_{0}, y_{0}\right) \in\left\langle e_{1}, e_{2}, \ldots, e_{\ell}\right\rangle_{\alpha, b, 2}\right\} \\
& <\mu_{\alpha, b, 2}\left(\left\langle e_{1}, e_{2}, \ldots, e_{\ell}\right\rangle_{\alpha, b, 2}\right)-\epsilon, \tag{33}
\end{align*}
$$

and

$$
\begin{align*}
\lim _{N \rightarrow \infty} & \frac{1}{N} \#\left\{0 \leq m \leq N-1:{\hat{G^{*}}}^{m}\left(\psi^{-1}\left(x_{0}, y_{0}\right)\right) \in\left\langle b_{1}, \ldots, b_{n}\right\rangle_{1,(1, n)}\right\} \\
& =\hat{\mu}\left(\left\langle b_{1}, \ldots, b_{n}\right\rangle_{1,(1, n)}\right) \tag{34}
\end{align*}
$$

for any sequence of positive integers $\left(b_{1}, b_{2}, \ldots, b_{n}\right)$, where $\hat{\mu}$ is the measure defined by $\frac{1}{\log 2} \frac{d x d y}{(x-y)^{2}}$. Note that $\langle\cdots\rangle_{1,(1, n)}$ means a cylinder set with respect to $\hat{G}^{*}=\hat{G}_{\alpha}^{*}$ with $\alpha=1$.

We start by assuming (32) and (34) hold, and show it will lead to a contradiction. Since the set of cylinder sets associated with $\hat{G}^{*}$ generates the Borel $\sigma$-algebra, there exist a finite number of pairwise disjoint cylinder sets

$$
\left\langle b_{j, 1}, b_{j, 2}, \ldots, b_{j, k_{j}}\right\rangle_{1,\left(1, k_{j}\right)}, \quad 1 \leq j \leq M<\infty, \quad 1 \leq k_{j}<\infty
$$

such that,

$$
\psi^{-1}\left(\left\langle e_{1}, e_{2}, \ldots, e_{\ell}\right\rangle_{\alpha, b, 2}\right) \subset \bigcup_{j=1}^{M}\left\langle b_{j, 1}, b_{j, 2}, \ldots, b_{j, k_{j}}\right\rangle_{1,\left(1, k_{j}\right)}
$$

and

$$
\hat{\mu}\left(\bigcup_{j=1}^{M}\left\langle b_{j, 1}, b_{j, 2}, \ldots, b_{j, k_{j}}\right\rangle_{1}\right)<\hat{\mu}\left(\psi^{-1}\left(\left\langle e_{1}, e_{2}, \ldots, e_{\ell}\right\rangle_{\alpha, b, 2}\right)\right)+\frac{1}{2} \epsilon .
$$

Since $\psi$ is an isomorphism (see Theorem [5), we have

$$
\hat{F}_{\alpha, b, 2}\left(x_{0}, y_{0}\right)=\psi \hat{G}^{*} \psi^{-1}\left(x_{0}, y_{0}\right)
$$

and

$$
\mu_{\alpha, b, 2}\left(\left\langle e_{1}, e_{2}, \ldots, e_{\ell}\right\rangle_{\alpha, b, 2}\right)=\hat{\mu}\left(\psi^{-1}\left(\left\langle e_{1}, e_{2}, \ldots, e_{\ell}\right\rangle_{\alpha, b, 2}\right)\right)
$$

Thus,

$$
\begin{aligned}
& \lim _{N \rightarrow \infty} \frac{1}{N} \#\left\{0 \leq m \leq N-1: \hat{F}_{\alpha, b, 2}^{m}\left(x_{0}, y_{0}\right) \in\left\langle e_{1}, e_{2}, \ldots, e_{\ell}\right\rangle_{\alpha, b, 2}\right\} \\
\leq & \lim _{N \rightarrow \infty} \frac{1}{N} \#\left\{0 \leq m \leq N-1:{\hat{G^{*}}}^{m}\left(\psi^{-1}\left(x_{0}, y_{0}\right)\right) \in \bigcup_{j=1}^{M}\left\langle b_{j, 1}, \ldots, b_{j, k_{j}}\right\rangle_{1}\right\} \\
= & \hat{\mu}\left(\bigcup_{j=1}^{M}\left\langle b_{j, 1}, b_{j, 2}, \ldots, b_{j, k_{j}}\right\rangle_{1}\right) \\
< & \hat{\mu}\left(\psi^{-1}\left(\left\langle e_{1}, e_{2}, \ldots, e_{\ell}\right\rangle_{\alpha, b, 2}\right)\right)+\frac{1}{2} \epsilon \\
= & \mu_{\alpha, b, 2}\left(\left\langle e_{1}, e_{2}, \ldots, e_{\ell}\right\rangle_{\alpha, b, 2}\right)+\frac{1}{2} \epsilon .
\end{aligned}
$$

Combining this with (32) yields $\epsilon<\frac{1}{2} \epsilon$, which is a contradiction.

On the other hand, if (33) and (34) hold, a proof similar to the one above but now approximating the cylinder $\psi^{-1}\left(\left\langle e_{1}, e_{2}, \ldots, e_{\ell}\right\rangle_{\alpha, b, 2}\right)$ from "inside" by a union of cylinders leads to the same contradiction.

Proof of Theorem 4. This is a direct consequence of Lemmas 3, 4, 5, and 6.
5.2. Non- $\phi$-mixing property. We start with some definitions of mixing properties. Let $(\Omega, \mathfrak{B}, P)$ be a probability space. For sub $\sigma$-algebras $\mathcal{A}$ and $\mathcal{B} \subset \mathfrak{B}$, we put

$$
\phi(\mathcal{A}, \mathcal{B})=\sup \left\{\left|\frac{P(A \cap B)}{P(A)}-P(B)\right|: A \in \mathcal{A}, B \in \mathcal{B}, P(A)>0\right\}
$$

Suppose that $\left(X_{n}: n \geq 1\right)$ is a stationary sequence of random variables. We denote by $\mathcal{F}_{m}^{n}$ the sub- $\sigma$ algebra of $\mathfrak{B}$ generated by $X_{m}, X_{m+1}, X_{m+2}, \ldots, X_{n}$. We define $\phi(n)=\sup _{m \geq 1} \phi\left(\mathcal{F}_{1}^{m}, \mathcal{F}_{m+n}^{\infty}\right)$ and $\phi^{*}(n)=\sup _{m \geq 1} \phi\left(\mathcal{F}_{m+n}^{\infty}, \mathcal{F}_{1}^{m}\right)$.

The process $\left(X_{n}: n \geq 1\right)$ is said to be $\phi$-mixing if $\lim _{n \rightarrow \infty} \phi(n)=0$ and reverse $\phi$-mixing if $\lim _{n \rightarrow \infty} \phi^{*}(n)=0$, respectively.
$G_{\alpha}$ is said to be $\phi$-mixing (or reverse $\phi$-mixing) if ( $a_{\alpha, n}, \varepsilon_{\alpha, n}$ ) is $\phi$ mixing (or reverse $\phi$-mixing), respectively. In [29], it is shown that $G_{\alpha}$ is not $\phi$-mixing for a.e. $\alpha, \frac{1}{2} \leq \alpha \leq 1$. On the other hand, $G_{\alpha}$ is reverse $\phi$-mixing for every $\alpha, 0<\alpha \leq 1$, which follows from [1].

In [29], it is shown that $G_{\alpha}$ is weak Bernoulli for any $\frac{1}{2} \leq \alpha \leq 1$ but is not $\phi$-mixing. It is not hard to show that $G_{\alpha}$ is weak Bernoulli for any $0<\alpha<\frac{1}{2}$ following the proof given in [29]. On the other hand, it follows that $G_{\alpha}$ is reverse $\phi$-mixing for any $0<\alpha \leq 1$; see [1]. In the proof of the next Theorem we outline how one can extend the proofs of [29] to the case $0<\alpha<\frac{1}{2}$.

Theorem 6. For almost every $\alpha, 0<\alpha<1, G_{\alpha}$ is not $\phi$-mixing.
Sketch of the proof. The proof of the non- $\phi$-property in [29] is based on the following two properties:
(i) For almost every $\alpha, \frac{1}{2} \leq \alpha \leq 1,\left(G_{\alpha}^{n}(\alpha): n \geq 0\right)$ is dense in $\mathbb{I}_{\alpha}$.
(ii) For every $\alpha, \frac{1}{2}<\alpha<\frac{\sqrt{5}-1}{2}, G_{\alpha}^{2}(\alpha)=G_{\alpha}^{2}(\alpha-1)$ and for every $\alpha, \frac{\sqrt{5}-1}{2} \leq \alpha<1, G_{\alpha}^{2}(\alpha)=G_{\alpha}(\alpha-1)$, respectively.
The first statement follows from the fact that the set of normal numbers w.r.t. $\alpha$ is independent of $\alpha([23])$. Because of Theorem 4 above, we can extend $(i)$ to almost every $0<\alpha \leq 1$.

The second statement is generalized in [8]: for almost every $\alpha$, there exists $n, m$ such that $G_{\alpha}^{n}(\alpha)=G_{\alpha}^{m}(\alpha-1)$. From this, we can show that
thin cylinders exist for almost every $\alpha$ and for any $\epsilon>0$. To be more precise, for any $\epsilon>0$, a cylinder set $\mathcal{C}=\left\langle c_{\alpha, 1}, c_{\alpha, 2}, \ldots, c_{\alpha, \ell}\right\rangle_{\alpha}$ is said to be an $\epsilon$-thin-cylinder if:
a) $G_{\alpha}^{\ell}(\mathcal{C})$ is an interval;
b) $G_{\alpha}^{\ell}: \mathcal{C} \rightarrow G_{\alpha}^{\ell}(\mathcal{C})$ is bijective;
and
c) $\left|G_{\alpha}^{\ell}(\mathcal{C})\right|<\epsilon$.

Once we have a sequence of $\epsilon_{n}$-thin cylinders with $\epsilon_{n} \searrow 0$, the proof is completely the same as one given in [29] if we choose $\alpha$ so that the matching property holds and $\alpha-1$ is $\alpha$-normal. For in this case, there exist $n_{0}, m_{0}$ such that $G_{\alpha}(\alpha-1)^{n_{0}}=G_{\alpha}^{m_{0}}(\alpha)$ (matching property). Moreover, there exists $n_{\epsilon}>\max \left(n_{0}, m_{0}\right)$ such that $\min \left(\mid \alpha-G_{\alpha}^{n_{\epsilon}}(\alpha-\right.$ $1)\left|,\left|(\alpha-1)-G_{\alpha}^{n_{\epsilon}}(\alpha-1)\right|<\epsilon\right)$, which follows from the normality of $\alpha-1$.

We suppose that $\left|(\alpha-1)-G_{\alpha}(\alpha-1)\right|<\epsilon$. Because of the matching property, see [8], either $\left\langle c_{1}(\alpha-1), c_{2}(\alpha-1), \ldots, c_{n_{\epsilon}}(\alpha-1)\right\rangle_{\alpha}$ or $\left\langle c_{1}(\alpha), c_{2}(\alpha), \ldots, c_{n_{\epsilon}}(\alpha)\right\rangle_{\alpha}$ is an $\epsilon$-thin-cylinder set. This is because of the following: If $\alpha$ is normal, then it means $\alpha$ is not rational nor quadratic. The iteration $G_{\alpha}^{n}$ associated with $\alpha$ and $G_{\alpha}^{m}$ associated with $\alpha-1$ are linear fractional transformations. Hence $\alpha \mapsto G_{\alpha}^{n}(\alpha)$ and $\left(\alpha \mapsto G_{\alpha}^{m} \circ "-1 "\right)(\alpha)$ define the same linear fractional transformation, otherwise $\alpha$ is a fixed point of a linear fractional transformation which means $\alpha$ is either rational or quadratic. We denote by $L_{r}, L_{\ell}$ and $S$ the linear fractional transformations which induce $G_{\alpha}^{n}(\alpha)$, $G_{\alpha}^{m}(\alpha-1)$ and $x \mapsto x-1$, respectively. Then $L_{r}\left(\left\langle c_{1}(\alpha), \ldots, c_{n_{\epsilon}}(\alpha)\right\rangle_{\alpha}\right)=$ $\left(L_{\ell} \circ S\right)\left(\left\langle c_{1}(\alpha), \ldots, c_{n_{\epsilon}}(\alpha)\right\rangle_{\alpha}\right)$. This shows that $G_{\alpha}^{n}\left(\left\langle c_{1}(\alpha), \ldots, c_{n_{\epsilon}}(\alpha)\right\rangle_{\alpha}\right)$ and $G_{\alpha}^{m}\left(\left\langle c_{1}(\alpha-1), \ldots, c_{n_{\epsilon}}(\alpha-1)\right\rangle_{\alpha}\right)$ have one common end point $G_{\alpha}^{n}(\alpha)$ and no common inner point. In the case of $\left|\alpha-G_{\alpha}(\alpha-1)\right|<\epsilon$, the same holds exactly. In this way, we can choose a sequence of $\epsilon_{n}$-thin cylinders and Theorem 6 follows in exactly the same way as in [29].
